sustainable forests with non-toxic inks.  
Our distribution policy aims to reduce  
UN Environment's carbon footprint.

**GLOBAL ENVIRONMENT OUTLOOK**  
**GEO-6**  
**HEALTHY PLANET, HEALTHY PEOPLE**

A healthy planet is important for the health and well-being of all people. It directly supports the lives and livelihoods of 70 per cent of the Earth's population

The top 10 emitting countries emit 45 per cent of global GHG emissions; the bottom 50 per cent emit only 13 per cent

Exposure to indoor/outdoor air and water pollution costs at least 9 million lives annually

Current science justifies policy action now. More detailed knowledge can enable more refined and ambitious policy

Achieving the 2°C Paris Agreement target could save US\$ 54.1 trillion for a global expenditure of \$US 22.1 trillion. Achieving a 1.5°C target could lead to a health saving of \$US 3.3-8.4 trillion for India and \$US 0.3-2.3 trillion for China

Meat production currently uses 77 per cent of agricultural land. Agricultural production consumes 70 per cent of global water.

# Acknowledgements

The sixth Global Environment Outlook (GEO-6) assessment report is a product of the generous dedication and extraordinary investment of numerous individuals, whose knowledge, expertise and insight helped shape this important body of work. UN Environment acknowledges the contributions made by many governments, individuals and institutions to the preparation and publication of this report. A more complete list of names of individuals and institutions involved in the assessment process is included following the annexes of this publication. Special thanks are extended to:

## High Level Inter-Governmental and Stakeholder Advisory Group (HLG)

Nassir S. Al-Amri, Hæge Andenæs, Juan Carlos Arredondo, Sara Baisai Feresu, Benon Bibbu Yassin, Simon Birkett, Gillian Bowser, Joji Carino, Fernando E.L.S. Coimbra, Marine Collignon (alternate), Victoria de Higa Rodriguez, Laksmi Dhewanthi, Noasilalaonomenjahary Ambinintsoa Lucie, Arturo Flores Martinez (alternate), Sascha Gabizon, Prudence Galega, Edgar Gutiérrez Espeleta, Keri Holland (alternate), Pascal Valentin Houénou (Vice-chair), Yi Huang (Co-chair), Ingeborg Mork-Knutsen (alternate), Melinda Kimble, Asdaporn Krairapanond, Yaseen M. Khayyat, Pierluigi Manzione, Veronica Marques (alternate), Jock Martin, John M. Matuszak, Megan Meaney, Naser Moghaddasi, Bedrich Moldan, Roger Roberge, Najib Saab, Mohammed Salahuddin, Jurgis Sapijanskas (alternate), Paolo Soprano (Co-chair), Xavier Sticker, Sibylle Vermont (Vice-chair), Andrea Vincent (alternate), Terry Yosie.

## Scientific Advisory Panel

Asma Abahussain, John B.R. Agard, Odeh Al-Jayyousi, Paulo Eduardo Artaxo Netto, Rosina M. Bierbaum, Enrico Giovannini, Sarah Green (Co-chair), Torkil Jørch Clausen, Ahmed Khater, Nicholas King (Co-chair), Paolo Laj, Byung-Kook Lee, Alastair Charles Lewis, Franklyn Lisk, Majid Shafiepour Motlagh, Carlos Afonso Nobre, Toral Patel-Weynand, Anand Patwardhan, N.H. Ravindranath (Vice-chair), Wendelin Stark, Danling Tang, Maria del Mar Viana Rodriguez (Vice-chair), Naohiro Yoshida.

## Members of the Assessment Methodologies, Data and Information Working Group

Maria Andrzejewska, Ousséni Arouna, Sandra De Carlo (Co-chair), Rosario Gomez, Wabi Marcos, Reza Maknoon, Graciela Metternicht, Thy Nguyen Van, Nicolas Perritaz (Co-chair), Qurat ul Ain Ahmad, Mathis Wackernagel, Fei Wang.

## Co-chairs and Vice-chairs of the assessment

Co-chairs: Paul Ekins, Joyeeta Gupta.

Vice-chairs: Jane Bemigisha, Kejun Jiang.

## Coordinating Lead Authors (CLAs)

Ghassem Asrar, Elaine Baker, Tariq Banuri, Graeme Clark, John Crump, Florence Mayocyc-Daguitan, Jonathan Davies, Phillip Dickerson, Nicolai Dronin, Mark Elder, Erica Gaddis, Jia Gensuo, Anna Maria Grobicki, Cristina Guerreiro, Andrés Guhl, Peter Harris, Rowena Hay, Steve Hedden, Klaus Jacob, Mikiko Kainuma, Terry Keating, Peter King, Pali Lehohla, Christian Loewe, Paul Lucas, Diana Mangalagiu, Diego Martino, Shanna McClain, Catherine McMullen, Adelina Mensah, Indu K. Murthy, Charles Mwangi, John Muthama Nzioka, Jacob Park, Laura Pereira, Fernando Figueira Prates, Walter Rast, Jake Rice, Joni Seager, William Sonntag, Peter Stoett, Michelle Tan, Detlef van Vuuren, Dimitri Alexis Zenghelis.

## Review Editors

Amr Osama Abdel-Aziz, Ahmed Abdelrehim, Majdah Aburas, Mohammad Al Ahmad, Chandani Appadoo, Michael Brody, Louis Cassar, William W. Dougherty, Manal Elewah, Amr El-Sammak, Elsa Patricia, Galarza Contreras, Jose Holguin-Veras, Muhammad Ijaz, Joy Jadam, Emmanuel Dieudonné Kam Yogo, Yoon Lee, Clever Mafuta, Simone Maynard, Joan Momanyi, Jacques André Ndione, Washington Odongo Ochola, Renat Perelet, Linn Persson, Jan Plesnik, Ariana Rossen, Mayar Sabet, John Shilling, Binaya Raj Shivakoti, Asha Singh, Asha Sitati, Lawrence Surendra, Paul C. Sutton, Khulood Abdul Razzaq Tubaishat, Emma Archer van Garderen, Lei Yu, Samy Mohamed Zalat.

## GEO-6 Funders

Producing an assessment of this scale requires many generous contributions. The following organizations provided funding directly or indirectly to the sixth *Global Environment Outlook*: The Government of Norway, the European Union, the Governments of Italy, Singapore, China, Mexico, Switzerland, Denmark, Egypt and Thailand. Together with UN Environment's Environment Fund and Regular Budget, these contributions allowed for the production of GEO-6 and its accompanying Summary for Policymakers, as well as subsequent outreach activities.

## GEO-6 Partners

GEO-6 also benefited from the generous contributions of several partners, including: GRID-Arendal, World Conservation Monitoring Centre (WCMC), The Centre for Environment and Development in the Arab Region and Europe (CEDARE), The Big Earth Data Science Engineering Program (CASEarth), the European Space Agency (ESA), the Netherlands Environmental Assessment Agency (PBL), the Freie Universität Berlin and the Massachusetts Institute of Technology (MIT).

## The sixth Global Environment Outlook Production Team

### **GEO-6 Core Team**

Pierre Boileau (Head of GEO Unit), Minang Acharya, Yunting Duan, Sandor Frigyik, Orlane Jadeau, Caroline Kaimuru, Jian Liu, Caroline Mureithi, Franklin Odhiambo, Brigitte Ohanga, Adele Roccato, Sharif Shawky, Simone Targetti Ferri, Brennan Van Dyke, Edoardo Zandri.

### **Chapter Coordinators**

Joana Akrofi, Hilary Allison, Jennifer Bailey, Pierre Boileau, Jillian Campbell, Kilian Christ, John Crump, Valentin Foltescu, Jason Jabbour, Hartwig Kremer, Maarten Kappelle, Patrick M'Mayi, Franklin Odhiambo, Mohamed Sessay, Michael Stanley-Jones, Simone Targetti Ferri, Kaisa Uusimaa, Clarice Wilson.

### **Production and Data Support**

Misha Alberizzi, Matthew Billot, Alexandre Caldas, Jillian Campbell, Ludgarde Coppens, Ananda Dias, Angeline Djampou, Dany Ghafari, Virginia Gitari, Florence Kahi, Isabell Kempf, Sera Kinoyan, Ian Magero, Nada Matta, Pascil Muchesia, Josephine Mule, Jane Mureithi, Theuri Mwangi, Immaculate Mwololo, Samuel Opiyo, Audrey Ringler, Jinhua Zhang.

### **Peer-review System and Database**

Ahmed Abdelrehim (CEDARE), Tesfaye Demissie (UNECA), Clever Mafuta (GRID-Arendal), Mayar Sabet (CEDARE), Ayman Soliman (CEDARE), Viola Sawiris (CEDARE), Youssef Younis (CEDARE).

### **Maps and Graphics**

Fang Chen (CASEarth/RADI), Pouran Ghaffarpour (UNON Publishing), Catherine Kimeu (UNON Publishing), Samuel Kinyanjui (UNON Publishing), Jie Liu (CASEarth/RADI), Jennifer Odallo (UNON Publishing), Audrey Ringler, Jinita Shah (UNON Publishing), Zeeshan Shirazi (CASEarth/RADI), Lei Wang (CASEarth/RADI).

### **Editorial Team**

Markus MacGill (Green Ink Limited), Clare Pedrick (Green Ink Limited), Anne Sweetmore (Green Ink Limited), Tim Woods (Green Ink Limited).

### **Design and Layout**

Jennifer Odallo, Catherine Kimeu (UNON Publishing Services Section), Audrey Ringler (UN Environment)

# Foreword

The sixth *Global Environment Outlook* is an essential check-up for our planet. Like any good medical examination, there is a clear prognosis of what will happen if we continue with business as usual and a set of recommended actions to put things right. *GEO-6* provides both a statement of the problems and a how-to guide to advance us on the path set out in the 2030 Agenda and the 17 Sustainable Development Goals.

The theme, “Healthy Planet, Healthy People”, highlights the inextricable link between the environment and our survival and progress. The challenges outlined are multiple. From climate change to the extinction of species, economies too dependent on the wasteful use of resources and unprecedented pressure on terrestrial and marine ecosystems, we are at a decisive moment in our role as custodians of the planet.

It is not all bad news. Many indicators point to progress on issues such as global hunger, access to clean water, sanitation and clean energy. We can also see some signs of the decoupling of environmental degradation and unsustainable resource use from economic growth, as well as unprecedented technological innovation.

The overall message, however, is that we need a significant shift in trajectory – indeed, the kind of transformational change prescribed by the Intergovernmental Panel on Climate Change in its recent report on limiting global warming to 1.5 degrees.

*GEO-6* details both the perils of delaying action and the opportunities that exist to make sustainable development a reality. We have the necessary policy guidance and the science that underpins it. The only missing ingredient for success is our collective resolve.

A handwritten signature in black ink, which appears to read 'António Guterres'. The signature is fluid and cursive, with a long horizontal stroke at the end.

January 2019

# Foreword

"Grow now, clean up later". That's sadly been the business model for much of the world since the industrial revolution. It's as if looking after environment is a needless distraction, but ultimately a nice add-on when economies are doing well, and when luxuries can be afforded.

The *Global Environment Outlook*, now in its sixth edition, has been a key driver of the shift in this mindset. Grounded in the best available science and real-world case studies, it underscores the fact that a healthy planet is a prerequisite for healthy people, and that is in turn the foundation of any healthy economy. And most importantly, it shows how it's possible to win on all fronts.

In this drive towards a green economy, greater sustainability and the hope that we can thrive rather than merely survive, there has never been a more critical moment than now. The science and data are crystal clear on the multitude of challenges we face, but also the small window of opportunity we have to turn things around.

The *Global Environment Outlook* is therefore a roadmap to achieving the United Nations' Agenda 2030, in which hunger and poverty are consigned to history, and where biodiversity, oceans, land and freshwater are protected and restored to health.

It makes it clear that achieving this requires a transformation in human lifestyles and productive activities: our industry, agriculture, buildings, transport and the energy system which powers them.

It means renewables like wind and solar must be the new norm, as must energy efficient, green buildings and transport. At the same time, this work also opens up huge economic opportunities – a new, better industrial revolution.

The task may be enormous, but we should also be inspired. Global environmental actions like the Montreal Protocol, our innovative defence against the hole in the Ozone layer, prove that we have the institutions and capacity to come together. The issue of plastics pollution has shown how diverse communities around the world – school children in Bali, coastal residents in Mumbai or surfers from Cornwall – can come together. After all, making the world a better place and cleaning up our act is a non-partisan, unifying cause we can all get behind.

**Joyce Msuya**  
Acting Executive Director, UN Environment

## Co-Chairs' Foreword

What is the Outlook for humanity? This sixth *Global Environment Outlook (GEO-6)* shows clearly that our species now stands at a crossroads. It can choose a challenging but navigable path towards a new golden age of sustainable development as envisaged by the United Nations' Agenda 2030 in which human hunger and poverty are consigned to history through the sustainable use of Earth's resources and the natural environment that leaves no-one behind. Or it can continue with current trends and practices, which will lead to a losing struggle against environmental disruptions, which threaten to overwhelm large parts of the world.

*GEO-6* clearly identifies the problems that have to be addressed if this latter outcome is to be avoided. But it also points to the solutions to these problems, to ways in which the aspirations of the Sustainable Development Goals (SDGs) can be realised and Earth's air, biodiversity, oceans, land and freshwater restored to health, to the incalculable benefit of Earth's people: Healthy Planet, Healthy People, the title of *GEO-6*.

*GEO-6* makes clear that achieving the SDGs will require a transformation in human lifestyles and productive activities: our industry, agriculture, buildings, transport and the energy system which powers them. This necessary transformation over the coming decades represents an enormous economic opportunity to those countries, policy makers and businesses who show the enterprise and innovative spirit to put in place the technologies, social practices and institutions that can make sustainable development a reality.

As co-chairs of the sixth *Global Environment Outlook* we have overseen the work of the tireless authors and experts who have contributed to this analysis. The scientific integrity of the process has been monitored by the Scientific Advisory Panel. The High Level Group helped us to find the language that can communicate to policymakers. The Secretariat provided the staying power to ensure that the entire process moved smoothly. Some States provided the necessary funding, encouraged us and hosted some of our meetings. We feel that the *GEO-6* has gathered the evidence to show what needs to be done, and what can be done. We respectfully present it to the world's decision makers, and ask them to face and address these challenges, for all of our sakes and future generations.

# Co-Chairs' Message

UN Environment's sixth *Global Environmental Outlook (GEO-6)* has reviewed the state of the health of the environment and the related health of the people, and the prospects for meeting the Sustainable Development Goals (SDGs) of the UN's Agenda 2030. As co-chairs, we draw six key messages from the report:

**First, a healthy planet supports healthy people:** A healthy planet is important for the health and well-being of all people. It directly supports the lives and livelihoods of 70 per cent of the Earth's population living in poverty [SPM 2.2.2; 6, 6.3.4, 6.6.3; boxes 6.5, 13.2], in particular those who are very poor, and it provides the basis for the production of the goods and services that are necessary for the global formal economy, which had a global GDP value of \$US 75 trillion in 2017. Overall the biosphere is essential for human survival and civilization and its value to humans is therefore effectively infinite. However, for some purposes it is useful to calculate the monetary value of ecosystem goods and services; as an example the total global ecosystem services have been valued at \$US (2007) 125 trillion/year [1.3.1]. This number does not capture the benefits of, for example, a climate suitable for agriculture or how melting glaciers affect the water security of more than a billion people [4.2.2], and so is clearly an underestimate. The value of lost ecosystem services between 1995 and 2011 have been estimated at \$US 4-20 trillion (Costanza *et al.* 2014). More particularly, the value of pollinators which provide crucial services for commercial and non-commercial food production, has been estimated at \$US 351 Billion/year to the commercial sector (Lautenbach *et al.* 2012).

**Second, an unhealthy planet leads to unhealthy people:** The planet is becoming increasingly unhealthy through the negative impacts of biodiversity loss (including pollinators, coral reefs and mangroves), climate change and other air pollution, water pollution, ocean pollution and depletion, and land use change. An unhealthy planet has huge social costs in terms of human health and well-being as well as on the formal economy and livelihoods worldwide. As with ecosystem goods and services, these costs are difficult to express comprehensively in monetary or other terms. However, *GEO-6* provides data that illustrate the sort of costs involved. For example, exposure to indoor/outdoor air and water pollution costs at least 9 million lives annually [4.1.1] including 300,000 in the G7 countries in 2015 (Organisation for Economic Co-operation and Development [OECD] 2017). About 2.8 million people died in 2015 from indoor air pollution [5.3.1] and about 2.8 million depend on unclean traditional biomass [21.2.3]. Many more millions suffer from ill-health and loss of livelihoods. Pollution-related costs have been estimated at \$US 4.6 trillion annually [1.3.1]. 29 per cent of land is degraded affecting the lives and livelihoods of 1.3-3.2 billion people [8.3.2] and slow onset disasters are triggering migration [9.3.4; 9.7.3]. In 2016, 24.2 million people were internally displaced in 118 countries as a result of sudden-onset disasters [4.1.2]. Such disasters affected not just the poor countries, but also rich countries like the USA and Japan. Between 1995-2015, 700,000 people died and 1.7 billion people were affected by extreme

weather events costing \$US 1.4 trillion [4.1.2; Figure 4.2] (Centre for Research on the Epidemiology of Disasters and United Nations Office for Disaster Risk Reduction 2015). Between 2010 and 2016, an average of around 700 extreme events each year cost an average of \$US 127 billion per annum. While 90 per cent of the losses came from high and upper-middle income countries, the less than 1 per cent of the losses from low-income countries amounted to around 1.5 per cent of their GDP, a much higher proportion than in high-income countries, and was almost all uninsured (Watts *et al.* 2017). The damage of climate variability and change to some small island regions is in the order of 1-8 per cent of GDP averaged over 1970-2010 (United Nations Environment Programme [UNEP] 2016a); if average global warming is not limited to 1.5°C, small island states and coastal populations may face existential threats. Water-related health costs are estimated at about \$US140 billion in lost earnings and \$US 56 billion in health costs annually (LiXil, Water Aid and Oxford Economics 2016). Such impacts are likely to exacerbate inequalities within and between countries, as opposed to reducing them in line with SDG10.

**Third, the drivers and pressures leading to an unhealthy planet need to be addressed:** The drivers and pressures result from a continuing failure to internalize environmental and health impacts into economic growth processes, technologies and city design. The pressures arise from massive use of chemicals (many with toxic health and environmental implications), huge waste streams (many largely unmanaged), committed and intensifying climate change impacts, and inequality which contributes to demographic changes and other drivers and pressures. The environmental footprint of rich people is significantly higher than that of poorer people. For example, the monthly emissions per capita in rich countries are mostly higher than the yearly emissions per capita in poorer countries (Ritchie and Roser 2018). The wealthiest countries consume 10 times the materials per person compared to the poorest countries (UNEP 2016b). While ideas around a green, healthy and inclusive economy aim to address these challenges, these ideas have yet to be systematically reflected in existing national policies. The IPCC 1.5°C report highlights

the very limited time left to reduce greenhouse gas emissions to the extent necessary to limit average global warming to this level, thereby avoiding the potentially very expensive adaptation costs that will otherwise be required (Intergovernmental Panel on Climate Change 2018).

**Fourth, current science justifies policy action now, but more detailed knowledge can enable more refined and preemptive policy.**

Existing knowledge is sufficient to mobilize action now [1,2, 4-9]. New knowledge including disaggregated data from earth observation, in-situ data, citizen science, ground truthing and indigenous and local knowledge are necessary in national policy and accounting more broadly [3]. There are major benefits in accounting systems that register the details about who causes damage to the environment, how and why; what is the extent of nature's contributions to humans, the loss of ecosystem goods and services; and who is affected [Figure 3.6]. Statistics and accounting systems also need to recognize the realities of the predominantly poor people in the informal economy, who are often particularly dependent on nature's contributions to people, and hence more vulnerable to environmental degradation.

**Fifth, environmental policy is necessary but inadequate by itself to address systemic ecological problems, solutions to which require a more holistic approach.**

Current (inter) national policies are not on track to address the key environmental challenges effectively and equitably, in line with the aspirations of the SDGs. Environmental considerations need to be integrated into all policy areas, such that the potential and actual implications for natural resources and the environment are robustly included in policies for economic growth, technological development and urban design, so that there is effective long-term decoupling between economic growth, resource use and environmental degradation. Climate mitigation needs to be accompanied by policy for the equitable adaptation to committed climate change. Policies will only be effective if they are well designed, involving clear goals and flexible mixes of policy, including monitoring, instruments aimed at achieving them [12-17] and when access to judicial remedies are available [23.3; 23.11; 24.2]. Such a holistic approach need not require additional economic costs. If 2 per cent of global GDP is invested in maintaining and restoring natural capital, it could deliver the same economic growth outcome as a similar investment along current lines

[18.1]. The health benefits from reduced air pollution of achieving the 2°C target could be 1.4-2.5 times the cost of mitigation, the higher figure involving benefits of \$US 54.1 trillion for a global expenditure of \$US 22.1 trillion. Moving from a 2°C to a 1.5°C target would generate further substantial health benefits for China and India [Box 24.1]. Food security could be enhanced if food wastage, currently running at 33 per cent globally, is curtailed [SPM 2.2.4].

**Sixth, healthy people, a healthy planet and a healthy economy can be mutually supportive:**

Healthy diets (less meat) and lifestyles, healthy cities with good waste management (2 out of five people lack access to waste disposal services [SPM 2.2.6; 4.4.1]) and the use of green infrastructure in built-up areas, and healthy mobility can increase labour productivity, reduce the need for land for agriculture (e.g. meat production currently uses 77 per cent of agricultural land [SPM 2.2.4; 8.5.1, 8.5.3]) and reduce the costs associated with urban congestion and transport-related pollution and address the potential trade-offs between land for food/biofuel and biodiversity protection (OECD 2017). Technological and social innovation that supports environmentally sound economic development provides a viable and attractive alternative to the 'grow now, clean up later' practices of the past. In addition, a healthy people approach requires implementation of the rights of access to clean water and food, tenure rights, and gender equality. Millions of lives could be saved and livelihoods improved by access to clean air, water, fuel and food. Secure tenure rights for poor and indigenous people would enhance their ability to protect biodiversity and the different ecosystems that sustain them – for example, indigenous and poor people live on 22 per cent of the land that supports 80 per cent of global biodiversity (Sobrevila 2008) generating billions of dollars' worth of carbon sequestration, reduced pollution, clean water, erosion control, etc. (SPM 2.2.4; 8.5.3). If gender equality is promoted, including the right to inherit and own land, then food security and many health issues relating especially to women and children could be better addressed [4.1.12]. Embracing the urgent and transformative changes that are required to accelerate the transition to a more equitable and environmentally sustainable economy, and a healthier society, through top down policy guidance and bottom-up initiatives will underpin the well-being and prosperity of countries and their people now and in the future.

## 1.1 GEO-6: Healthy Planet, Healthy People – humanity's transformative challenge

Providing a decent life and well-being for nearly 10 billion<sup>1</sup> people by 2050, without further compromising the ecological limits of our planet and its benefits, is one of the most serious challenges and responsibilities humanity has ever faced. People worldwide rely on the smooth functioning of Earth's natural life-support systems, in different ways and in different contexts. A healthy planet is a necessary foundation for the overall well-being and further advancement of humanity (United Nations 2015a; Organisation for Economic Co-operation and Development [OECD] 2017a).

Under the theme of 'Healthy Planet, Healthy People,' the sixth Global Environment Outlook (GEO-6) is an integrated assessment which considers various scientific perspectives and inputs from across the world in a holistic manner. The assessment urges the world's decision makers and all citizens to apply the principles of sustainable development to help ensure that Earth's environment remains the foundation of society and of people's well-being and resilience.

GEO-6 aims to answer the following questions:

- ❖ What is the state of the global environment, how is it changing, and what are the major factors and drivers, both positive and negative, influencing these changes?
- ❖ How are people and their livelihoods affecting and affected by environmental change in terms of health, economic prosperity, social equity, food security and overall well-being?
- ❖ Are environmental benefits, responsibilities and risks distributed fairly across different regions, socioeconomic groups and genders?
- ❖ What are the main responses and policy measures that have been taken to strengthen environmental protection and governance at various levels? How effective have they been in terms of improving environmental quality, and resource efficiency?
- ❖ What are the possible pathways, critical opportunities and policies, including Multilateral Environmental Agreements (MEAs) and Sustainable Development Goals (SDGs), to transform the global human-environment system to become more sustainable and contribute to a healthy planet for healthy people? What are the likely consequences if no additional actions are taken?

The first three points above are addressed by the introductory chapters and those in Part A of this report. The chapters in Part B consider the fourth point, on policy effectiveness, and the final point, on the most promising future pathways, is covered in Part C.

GEO-6 comes at a time of great uncertainty about the current trajectory of global human development (United States National Intelligence Council 2017). One major reason is that over the last few decades, human activities, such as human-caused climate change and other human impacts on ecosystems, have transformed the Earth's natural systems, exceeding their capacity and disrupting their self-regulatory mechanisms, with irreversible consequences for global

humanity (Intergovernmental Panel on Climate Change [IPCC] 2014). Humanity has already been seriously affected by ongoing systemic ecological changes, such as climate change and land use change (especially deforestation). These have reached the point that the ecological foundations of human society and natural systems that support other species and provide invaluable ecosystem services are in great danger (Millennium Ecosystem Assessment 2005).

Human activities are causing increasing amounts of pollution, to the extent that this is now recognised as the biggest single risk to human health worldwide (Landrigan *et al.* 2018). Continuing to live on the brink of or outside of ecological limits, from the global to the local, will make it dramatically more difficult to achieve prosperity, justice, equity and a healthy life for all (Crutzen and Stoermer 2000; Crutzen 2002; Steffen, Crutzen and McNeill 2007; Steffen *et al.* 2011; Steffen *et al.* 2015; Steffen *et al.* 2018). The need for humanity to remain within the planetary boundaries' safe operating space and the need to eradicate poverty and accelerate social and economic development are linked by the concept of "a safe and just space for humanity" (Raworth 2012).

To cope with this range of human-induced damages, including climate change, deforestation, desertification, loss of biodiversity, scarcity of natural resources, pollution, and the consequent natural and the associated environmental impacts, is a great challenge. While many old and new societal contradictions and conflicts have to be solved simultaneously (Beck 2009; Beck 2015; Raskin 2016), these accumulative and omnipresent challenges should be addressed as humanity's transformative challenge (Beck 2009), by creating opportunities for further human development which achieve human well-being. This would be, where the universally applied principles of sustainability govern the pathway towards 'Healthy Planet, Healthy People', with no one left behind and endeavouring to reach the furthest behind first (United Nations 2015a).

GEO-6 addresses this transformative challenge, which is taken up by the United Nations 2030 Agenda for Sustainable Development (2030 Agenda) and its 17 SDGs. Transforming human-environment interactions (and related human-human interactions), especially consumption and production patterns and lifestyles, towards sustainability requires a better information base and new, diversified knowledge of planetary systems (Steffen 2000; Schellnhuber *et al.* eds. 2004) and transformative processes within globalized social and economic systems (Schneidewind 2013). This includes the cultural dynamics and ethical foundation of human perceptions and understanding of 'nature and environmental sustainability' (Morton 2009; Lammel *et al.* 2013; Díaz *et al.* 2015; Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services [IPBES] 2015; Pascual *et al.* 2017).

The increasing body of global environmental assessments undertaken by international organizations in cooperation with the global science community and UN Member States provides the knowledge to understand the vital inter-connections and accelerating dynamics of natural ecosystems, socio-ecological systems and the dependence of human life on healthy and natural ecosystems. Increasing use of Earth observation techniques, from outer space and on Earth, in combination

<sup>1</sup> Throughout this publication the term 'billion' refers to 1000 million.

with new tools for data analysis, disciplines like environmental accounting (e.g. Kim and Kim eds. 2016), and environmental economics (Siebert 2008; Wiesmeth 2012; Ghosh *et al.* eds. 2016), has revolutionized our ability to recognize patterns of what causes environmental change and how it impacts life (Chuvieco ed. 2008; Tomás and Li 2017; Mathieu and Aubrecht eds. 2018).

Integrated and systems-based approaches (i.e. those that consider multiple benefits at the same time) enable cross-linkages to be explored and system-wide effects to be managed, so that policies can effectively support a number of social, economic and environmental goals to support human well-being, ensuring that various preconditions for this well-being are in place. These new scientific approaches and methods, including the study of cross-cutting inter-relationships between many areas, facilitate the preparation of more appropriate, equitable and effective policy responses, including shifting investment, production, distribution and consumption towards more sustainable approaches, and the development of better governance capacities at multiple scales. The GEO-6 assessment endeavours to support the vision that equal opportunities for prosperity and well-being for all, within the Earth's ecological limits, will be possible

through sustainable development pathways that are shared and pursued globally.

GEO-6 is intended to be solution-oriented, with these solutions drawing on facts and statistics. Based on multidisciplinary perspectives from various scientific fields, GEO-6 also provides an interpretative framework and tells stories, including successes, failures and aspirations, to help people, governments and the global community work to prevent and repair environmental damage and respond more effectively to environmental changes and opportunities. GEO-6 highlights existing evidence of these environmental changes and reflects on possible pathways and critical opportunities for transformation of the global human-environmental system to become more sustainable in the mid to long term (2030/2050).

GEO-6 is entitled 'Healthy Planet, Healthy People', a conceptual approach that considers the human dimensions for achieving a healthy planet. It underlines the importance of maintaining the integrity of ecosystems and recognizes their interlinkages with socioeconomic systems. It emphasizes that a healthy planet is a necessary foundation for human physical, psychological, social, economic and emotional health and well-being, and is therefore critical for achieving all the SDGs.

Raisa Lara Lütolf/Unsplash

Figure 1.1: Choices to be made to achieve a healthy planet for healthy people

**Figure 1.1** illustrates how a healthy planet contributes directly to healthier people by encouraging healthier lifestyles. Environmental degradation increases the burden of disease through exposure to harmful pollutants, as well as through reduced access to the ecosystem contributions from nature. Avoiding these problems will require protecting natural capital through detoxification, decarbonization, dematerialization and restoration of ecosystems to enhance planetary and human well-being.

A healthy planet requires protection and sustainable management of natural capital, in the form of nature's contributions to people, and human capital. People's opportunities in life are affected by humanity's ability to generate sustainable, long-term economic and social prosperity from human, physical and natural assets, the extent of environmental degradation and resource depletion, pollution and climate impacts, in addition to disparities in income and wealth.

This report recognizes that the environmental, economic and social equity dimensions are integrally linked, as they are in the SDGs with their overarching objective to 'Leave no one behind', and that all SDGs are rooted in human rights and dignity. Furthermore, many SDGs have environmental targets, some of which have equity components. Throughout GEO-6, evidence is presented of how fundamentally nature's contributions to people underpin human health and well-being. The SDGs recognize that inequality, including poverty and gender discrimination, results in a sizeable waste of human productivity and prosperity, and limits the scope for effective and accountable civic governance, quite apart from the ethical dimension of fairness and opportunity. Human resources are being underutilized and are not contributing to the sum total of human innovation required to help us live sustainably, demonstrated by the continued poverty in many parts of the world, which Agenda 2030 aims to eradicate (World Bank 2016a). The SDGs also recognize that disparities in access to resources, ecosystem services, income and wealth play an important role in shaping people's opportunities in life (Whitmee *et al.* 2015; OECD 2017), disproportionately affecting women and girls, as well as poor people.

## 1.2 UNEP's flagship assessment to deliver the environmental dimension of the 2030 agenda

Recognizing these important challenges, governments of the world have sought to better understand the interrelationships across the environmental dimension of the Sustainable Development Goals by requesting the preparation of a sixth edition of the Global Environment Outlook.

### 1.2.1 Mandate

Member States attending the first session of the United Nations Environment Assembly (UNEA-1) in Nairobi, June 2014, requested:

... the Executive Director, within the programme of work and budget, to undertake the preparation of the sixth Global Environment Outlook (GEO-6), supported by UNEP Live, with the scope, objectives and procedures of GEO-6

to be defined by a transparent global intergovernmental and multi-stakeholder consultation informed by document UNEP/EA.1/INF/14, resulting in a scientifically credible, peer-reviewed GEO-6 and its accompanying summary for policy makers, to be endorsed by the United Nations Environment Assembly no later than 2018.

As requested by Member States (UNEP/EA.1/4) and based on the decision (UNEP/IGMS.2 Rev.2) made by the Global Intergovernmental and Multi-stakeholder Consultation in Berlin, 21-23 October 2014, GEO-6 builds on six regional assessments that were conducted in a similar fashion to the global GEO-6 process and launched in May-June 2016. In addition, the main messages of GEO-6 are compiled in an accompanying Summary for Policymakers, which is drafted by the authors of the main report and negotiated by the governments. See Annex 1-1 for more details on UN Environment's mandate to produce the sixth Global Environment Outlook.

More recently, recognizing that the date of the fourth session of the UN Environment Assembly (UNEA-4) would be shifted to 11-15 March 2019, Member States decided at UNEA-3 to:

... [Request] the Executive Director to issue the sixth Global Environment Outlook report at least three months before the fourth session of the United Nations Environment Assembly;

Also [request] the Executive Director to schedule the negotiations on the summary for policymakers at least six weeks in advance of the fourth session of the United Nations Environment Assembly and to present the sixth Global Environment Outlook report and its accompanying summary for policymakers for consideration and possible endorsement by the Environment Assembly at its fourth session.

With these decisions, the delivery date of the embargoed version of the main report is now the week of 5 December 2018, and the delivery date of the adopted and translated version of the Summary for Policymakers is 28 January 2019.

### 1.2.2 Role of GEO-6

GEO-6 comes at a critical time for global development, and it will build on the knowledge and experience gained from previous GEOs. Previous GEO editions have already presented substantial evidence that environmental degradation, even within the planetary limits of the Earth's ability to support human civilization, has undermined current and future development, and threatened different aspects of human well-being (United Nations Environment Programme [UNEP] 2007; UNEP 2012a).

GEO-6 explores some issues further, attempting to show the interlinkages across environmental challenges and geo-political, economic, industrial, social, technological and cultural issues, while considering potential transformative sustainable development pathways and policies for achieving the SDGs and other Internationally Agreed Environmental Goals (IAEG). In this respect, GEO-6 aims to apply a wider scope to the discussion of global environmental security (Matthew *et al.* 2010; UNEP *et al.* 2013)

## Box 1.1: Concept of Well-being

Human well-being is assumed to have multiple constituents, including:

- ❖ the basic material for a good life, such as secure and adequate livelihoods,
- ❖ enough food at all times, shelter, clothing, and access to goods;
- ❖ health, including feeling well and having a healthy physical environment, such as clean air and access to clean water; good social relations, including social cohesion, mutual respect, and the ability to help others and provide for children;
- ❖ security, including secure access to natural and other resources, personal safety, and security from natural and human-made disasters; and freedom of choice and action, including the opportunity to achieve what an individual values doing and being.

Freedom of choice and action is influenced by other constituents of well-being (as well as by other factors, notably education) and is also a precondition for achieving other components of well-being, particularly with respect to equity and fairness.

Source: Millennium Ecosystem Assessment 2005

Additionally, GEO-6 attempts to further strengthen understanding of the macro perspective of socio-ecological systems (including economics), and also to use a more people-centred approach (UNEP 2016a). GEO-6 underlines that people are part of ecosystems and depend on them, emphasizing the importance of conserving nature not only for its intrinsic value, but also because it is crucial for the well-being of humanity. Such an approach is urgently needed to help address the vulnerability and different conditions and capabilities enabling people to react to hazards and disruptions in daily life (resilience) (Millennium Ecosystem Assessment 2005). With this knowledge, it is hoped that people will be encouraged to respond to the challenge by changing their behaviour as citizens, consumers, voters, politicians, religious leaders and business leaders (UNEP 2016b).

GEO-6 highlights an updated understanding of the relationship between the environment and the economy, which is a foundation of the people-centred approach. This emphasizes nature's contribution to people, the environmental functions that support human well-being (including the benefits of environmental investments, innovations and technologies), as well as the high costs of inaction, business as usual, and stranded assets.

Furthermore, this perspective within GEO-6 helps to better inform future policy decisions by addressing complex distributional impacts and conflicts as the new baseline to design sustainable development policies and governance systems associated with implementation of the 2030 Agenda (World Bank 2016b). Creating such knowledge and its evidence base through this assessment will help to better communicate possible policies, actions and investments that could be used by governments, as well as other stakeholders and citizens, to address current and future development challenges, as well as to explain the benefits of taking such actions. How this perspective is integrated into the GEO-6 assessment is further explained in Section 1.7.

### 1.3 GEO-6 in a changing global context

The world is facing a wide range of economic, social, cultural and political/military security challenges (World Economic Forum 2017). Despite significant global progress in economic development and poverty reduction in some regions, a large portion of the population in many areas suffers from poverty or extreme poverty, and many people who are not impoverished are still concerned about economic security and future life opportunities. Some areas are experiencing social friction,

growing inequality, poor governance, cultural erosion, reactions against globalization, political instability, large numbers of refugees, large-scale migration and violent conflicts due to these economic and social insecurities, injustices and corruption.

Many of these global economic, social and political/military security challenges are related to the environment in terms of causes, impacts and possible solutions. Moreover, recent scientific concepts of environmental safeguards for society, for example planetary boundaries (Rockström *et al.* 2009; Steffen *et al.* 2011; Steffen *et al.* 2015), explain that the environment is the foundation for human life on Earth. Current methods of generating material prosperity have undermined ecosystem health and caused massive environmental damage, crossing several of these planetary boundaries, to the point where the development of human societies and the 'safe operating space' for human life on Earth is at risk. In this planetary boundaries framework, environmental problems are considered to be inherent systemic problems of humans' deep-rooted transformation of nature and ongoing cultural dynamics, and are not seen only as collateral damage of societal development (Steffen 2000). Biodiversity is also critical for human well-being (Secretariat of the Convention on Biological Diversity [CBD] 2014), as are ecosystem services more broadly (Millennium Ecosystem Assessment 2005).

Clearly, the functions of environmental policy have expanded, and it now contributes to political/military security, economic and social policy and other development activities. Likewise, these other policy areas also have a major influence on the state of the environment. A key implication of these interlinkages is the need for an integrated approach to address environmental, economic and social problems holistically (United Nations 2015b; Jetzkowitz *et al.* 2018). GEO-6 aims to integrate the linkages between the environment, social and economic security, global justice and human well-being, to promote a new framework for sustainability to be an integral part of all aspects of global, regional and national development (United Nations Educational, Scientific and Cultural Organization [UNESCO] 2014a; Lehmann *et al.* 2015; UNEP 2016a; UNESCO 2016).

#### 1.3.1 Environmental and economic challenges and opportunities

The environment is closely related, in both positive and negative ways, to key economic issues such as poverty, prosperity, jobs, production patterns, innovation, and resource availability/scarcity. On one hand, the economy is a major

source of environmental problems, while environmental problems are increasingly causing economic losses. Recent articles have noted that “welfare losses due to pollution are estimated to amount to US\$4.6 trillion per year,” which is “about 6.2 per cent of global economic output” (Landrigan *et al.* 2018, p. 462). Economically, countries are often still guided by an approach of ‘grow now, clean up later’. This report will show that this is simply not sustainable in a world already crossing planetary boundaries on a number of dimensions, a situation which threatens to undermine economic growth if not addressed. In addition, this option is likely to prove far more expensive for most countries, because it is often costlier to clean up later than prevent damage in the first place; it creates stranded assets which lose their value, and is now leading to irreversible negative impacts, including on human health. This renders an economy unproductive and uncompetitive compared with a flexible and proactive approach, capable of managing the transition to a sustainable, innovative and resource-efficient economy that can take advantage of domestic and export market opportunities in fast-growing, environmentally aware markets.

On the other hand, protecting the environment, as well as preventing and mitigating the impacts of pollution, are also major sources of economic opportunity, providing jobs, reducing poverty, driving innovation and addressing resource availability/scarcity and depletion. Positive synergies between the economy and the environment are now more widely recognized (Porter and van der Linde 1995; The Economics of Ecosystems and Biodiversity [TEEB] 2010; OECD 2011; UNEP 2011a; UNEP 2011b; Hepburn and Bowen 2012; United Nations Economic and Social Commission for Asia and the Pacific [UNESCAP] and Korea International Cooperation Agency [KOICA] 2012; Global Commission on the Economy and Climate 2014; Altenburg and Assmann 2017; OECD 2017b), compared with the view that trade-offs exist between the environment and the economy.

The global economic value of ecosystem services was estimated to be about US\$ 125 trillion in 2011 (in 2007 US\$<sup>2</sup>) (Costanza *et al.* 2014). Still, more effort is needed to communicate this message about positive synergies, as the perspective of the trade-off between the economy and the environment is still reinforced by current methods of calculating economic growth, which generally externalize environmental impacts and emphasize short-term, rather than long-term, perspectives. Especially in nations/regions where people have anxieties about jobs, wages and economic prosperity, there is a risk of weakening support for environmental protection and MEAs if the linkages among these concerns are not well understood. GEO-6 aims to contribute to a more thorough assessment of costs and benefits, as well as the cost-effectiveness of environmental policies and practices, and how they are distributed in society.

Many businesses around the world now understand that environmental problems pose major challenges to their operations, and that addressing them presents significant business opportunities, for example through circular economy business practices (see Chapter 17), in the context of sustainable consumption and production (Lacy and Rutqvist

2015; Ghisellini, Cialani and Ulgiati 2016; Murray, Skene and Haynes 2017; Hopkinson, Zils and Hawkins 2018, see section 17.5 of this report), as well as enabling increases in productivity and profitability (at least in the initial stages of waste reduction and efficiency improvements). It also avoids major liabilities and burdens for future generations. Prominent business groups, such as the World Business Council for Sustainable Development and UN Global Compact, promote environmental sustainability at all levels of society and decision-making.

Environmental protection and environmental business can also be major sources of jobs (International Labour Office [ILO] 2016). In the global energy sector, renewable energy sources are growing much faster than expected, and global annual investment in these systems is now greater than investment in fossil fuels (Renewable Energy Policy Network for the 21<sup>st</sup> Century [REN21] 2018). It is suggested that ‘clean’ energy (renewable and low-carbon energy) and energy efficiency may have more job creation potential than coal and natural gas (Wei, Patadia and Kammen 2010; Garrett-Peltier 2017; International Renewable Energy Agency [IRENA] 2018; Yihdego, Salem and Pudza 2017). Most recently, in the United States of America, the solar industry accounts for more than twice as many jobs as coal (United States Department of Energy 2017).

Still, many economic trends pose challenges for addressing environmental problems. Many governments face challenges in raising revenue, and deregulation initiatives often focus on weakening environmental standards/regulations (Castree 2008; Steinebach and Knill 2017). The Addis Ababa Action Agenda, which addresses the means of implementation for sustainable development in general, including the SDGs, suggests ways to help governments strengthen their domestic financing capacity (United Nations 2015c).

Globalization has been an overall trend for several decades, and its possible environmental effects have been a major research focus. However, the linkages between economic development and the environment are very complex and difficult to summarize. Some aspects of globalization may worsen environmental problems, while others may be beneficial (Boyce 2004; Gallagher 2009; Clapp and Dauvergne 2011; Newell and Roberts eds. 2016). Identifying such trade-offs and synergies is a major element of the GEO-6 assessment (see chapters 4 and 17).

### 1.3.2 Environment and social challenges and opportunities

Environmental issues are closely related to social issues such as hunger, consumption patterns, health, education, inequality, gender gaps, waste and sanitation, refugees, migration, conflicts and intolerance. For example, hunger and food, addressed in SDG 2, are linked to agriculture, which in turn is linked to the environment, especially SDG target 2.4 on sustainable agriculture. Environmental pollution harms agriculture, while a cleaner environment will help to improve agriculture, nutrition and health (Landrigan *et al.* 2018).

Education promotes a healthier environment and vice versa (UNESCO 2014b; UNEP 2017a). Environmental pollution, biodiversity loss and climate change are important causes of health problems and environmental diseases, which in turn can negatively affect education and learning, especially

<sup>2</sup> Readers should assume that all values in this report are nominal market values, unless it is stated to the contrary.

among children; they can also be a hindrance to employment among adults (Mohai *et al.* 2011; Zhang and Zhang 2018). In contrast, cleaning up, avoiding pollution, and protecting and restoring habitats are major opportunities to improve health, which in turn helps people lead fuller and more productive lives. Diseases related to air pollution caused 9 million premature deaths in 2015, accounting for 16 per cent of all deaths globally (Landrigan *et al.* 2018) while in some countries, hazardous air pollution has forced schools to close (Sastry 2002; Li *et al.* 2014; British Broadcasting Corporation [BBC] 2016; Reuters 2017).

The environment is also related to growing social inequality, including gender inequality, in many ways that may put burdens on poor or socially disadvantaged people. These can include unequal access to resources (e.g. land, water, food, seeds), uneven distribution of the impacts of environmental degradation (e.g. the health impacts of climate change and waste), job creation and loss due to shifting consumption and production between geographic areas, and uneven distribution of responsibilities with respect to addressing environmental challenges. Children are particularly susceptible to the negative health impacts of chemicals, due to their rapid growth and development and greater exposure relative to body weight.

In many cases, people's environmental impacts are related to their income levels (Moser and Kleinhügelkotten 2017). Wealthier people are more able than poor people to insulate themselves from environmental problems, while they have more potential to contribute to solutions through their greater resources and scope for lifestyle changes (UNEP 2016b). This is also related to the geographic, economic and social distribution of areas affected by environmental problems.

The drivers and pressures of environmental change, as well as its state and impacts, have people-centred aspects that need to be taken into account in order to develop effective and just policies in an Agenda 2030 world. This approach is needed to help address the vulnerability and different conditions and capabilities of people to react to hazards and disruptions in daily life (resilience) (Millennium Ecosystem Assessment 2005). People – poor and rich, women and men – affect and are affected differently by environmental changes and related risks. These differences play a major role in related political decisions (Serret and Johnstone eds. 2006; UNEP 2016b). Using this perspective, GEO-6 attempts to interpret how environmental 'equity' will be experienced by different people, so it can inform future policy decisions by addressing complex distributional impacts and conflicts. This perspective provides a new baseline to design sustainable development policies and governance systems for implementing the 2030 Agenda (World Bank 2016).

In Agenda 2030, the sustainable use of the environmental and natural resources is now understood to be complementary and necessary to "end poverty in all its forms everywhere" (SDG 1). Approximately 70 per cent of the world's poor people depend directly on natural resources for all or part of their livelihoods, particularly women and girls, as well as other marginalized groups. Efforts to eradicate poverty and ensure prosperity are directly linked to improving the management of both the environment and natural resources in an integrated way (TEEB 2010).

### 1.3.3 Environment and political/military security challenges and opportunities

Environmental problems such as land degradation (United Nations Convention to Combat Desertification [UNCCD] 2017) and resource scarcity and depletion, especially water, energy, food and biodiversity, have the potential to be major sources of conflict, security problems and migration (Homer-Dixon 1991; Homer-Dixon 1999; Barnett and Adger 2007; Gupta, Dellapenna and Heuvel 2016). Political/military security problems may be amplified by climate change effects. Water security is being compromised by pollution and unsustainable use, as well as demand exceeding sustainable supply, climate variability, droughts, flooding, etc. Climate change, including related weather extremes, and environmental degradation are already having a range of complex effects, especially in fragile states and ecosystems. For example, they worsen the problems of migrants and refugees (both within and between countries), which in turn contribute to increasing political uncertainty and instability worldwide. Environmental refugees displaced by environmental degradation may also suffer from health problems and difficulties maintaining their livelihoods.

Wars and conflicts are major sources of pollution, especially air, water and soil pollution, waste, greenhouse gases and land degradation. Likewise, addressing environmental problems may provide important opportunities to help address political/military security problems (Brown, Hammill and McLeman 2007; UNEP *et al.* 2013), including by helping to secure livelihoods and reduce the necessity for migration. International funding to war-torn states may be productively aimed at addressing environmental problems through development of sustainable infrastructure, including natural infrastructure and ecosystem restoration, and services such as waste, wastewater and resource management.

### 1.3.4 Resource availability and scarcity

Resource availability and scarcity problems clearly illustrate the tight interlinkages between economic, social, human, political/military security and environmental issues (Qasem 2010; UNEP 2011a; Pereira 2015). Resources have significant negative environmental and social/health impacts in their production and/or use, for example through mining or other extraction processes.

At the same time, they are important inputs to environmental solutions. Resources are important economic inputs and sources of jobs, and are used in products and services supporting human well-being. This is not just related to the key resources of water, energy and food, which have been extensively researched as 'nexus' issues (UNESCAP 2013; Food and Agriculture Organization [FAO] 2014; International Resource Panel 2015). Phosphorus (Cordell and White 2015) is a key input for food production and other important scarce resources including materials such as rare earth metals (Gupta and Krishnamurthy 2004; Abraham 2015; Graedel *et al.* 2015), are used in many industrial applications including key environmental technologies such as wind and solar energy as well as advanced batteries. These materials, and the many products made from them, also have important military applications. On the negative side, in addition to the environmental damage caused by their production, these

resources are also scarce (Calvo, Valero and Valero 2017), leading to political/military security concerns related to securing their availability.

## 1.4 Environmental governance

Environmental governance is increasingly important at all levels, including global, regional, national and subnational (local, provincial, etc.) governments, as well as business and civil society stakeholders (Biermann *et al.* 2012; Biermann 2014; United Nations Economic Commission for Europe [UNECE] 2014; Patterson *et al.* 2015; Mortensen and Petersen 2017). New environmental governance challenges are emerging, such as the opening of the Arctic and the advent of new materials, while many old challenges have not been adequately addressed. Greater multi-stakeholder participation in governance is a major global trend, but there is a need for greater synergies between governments and civil society organizations. Many efforts have been made to develop more effective facilitation methods to enable this collaboration (Ansell and Gash 2008; UNECE 2014; Pattberg and Widerberg 2016; Dodds, Donoghue and Leiva-Roesch 2017). This includes new technologies and social media, and citizen science, which engages citizens in scientific research (Kobori *et al.* 2016, see section 25.2) which may be the only way to obtain some kinds of data. Also, governance within the private sector has become an important innovation space.

Environmental problems have always been very complex and closely related with other policy areas (Jordan and Lenschow 2010), but efforts to overcome separate sector/silo boundaries have not made sufficient progress (Adelle and Nilsson 2015). It is now more important than ever to promote the integration and coordination of environmental concerns with other development areas, such as economy, trade, health, water, energy, education, food systems and urban planning (FAO 2014; Le Blanc 2015; OECD 2015; Elder, Bengtsson and Akenji 2016; United Nations 2016; Scheyvens *et al.* 2017).

Moreover, ecosystem boundaries often do not correspond to geopolitical boundaries, so many environmental problems, especially those related to pollution, are often transboundary in nature, such as air pollution, freshwater contamination (surface and groundwater), marine pollution, wastewater, leakages of pollutants, dumping of hazardous and nuclear wastes and species loss. Because many of these transboundary problems are interrelated, there are extensive opportunities to take advantage of co-benefits from policy solutions, but these require greater cooperation and coordination across political boundaries.

Many efforts have been made to develop ways to improve environmental governance, ranging from stronger regulation and enabling policies to support voluntary actions, to stakeholder self-governance. The state has an important role in strengthening environmental governance, including by ratifying and implementing environmental conventions, supporting environmental research and supporting vulnerable populations. Still, the best way forward is not always clear, and further efforts are needed (Ansell and Gash 2008; Jordan 2008; Newig and Fritsch 2009; Biermann *et al.* 2012; Galaz *et al.* 2012; Biermann 2014; United Nations Development Programme [UNDP] 2014; Kanie, Andresen and Haas eds. 2014; Pattberg and Widerberg 2015; Pattberg and Zelli eds. 2016; Biermann, Kanie and Kim 2017).

## 1.5 The environmental dimension of the sustainable development goals, global environmental governance and multilateral environmental agreements

Until recent years, global environmental governance has mainly focused on MEAs (Najam, Papa and Taiyab 2006; Environment Canada, University of Joensuu and UNEP 2007; Kanie 2007), along with many regional and bilateral agreements (Balsiger and VanDeveer 2012). It has been estimated that there are over 1,300 MEAs and 2,200 bilateral environmental agreements (Mitchell 2018).

Despite these MEAs and five previous Global Environment Outlooks, the state of the environment remains troubled and has continued to deteriorate in many respects (Susskind and Ali 2015; UNEP 2012b), to the point where the environmental foundation for human society is increasingly at risk (Rockstrom *et al.* 2009; Steffen *et al.* 2011; Steffen *et al.* 2015). Moreover, some environmental pollutants, such as plastic waste, marine pollution, military-related waste and pesticides, remain largely unregulated at the global level. There has been insufficient progress in achieving sustainable consumption and production patterns.

Some international agreements and frameworks are working to deal with global problems more comprehensively, rather than focusing narrowly on specific environmental issues. They combine political, economic, social and environmental dimensions, while strengthening the environmental elements. These include the SDGs, the Paris Agreement on climate change, the Sendai Framework for Disaster Risk Reduction, the New Urban Agenda - Habitat III, and the United Nations Convention to Combat Desertification.

The SDGs and the 2030 Agenda are at the vanguard of this trend, bringing an integrated, holistic perspective to sustainable development. They link the environment with other dimensions of sustainable development in order to take advantage of synergies and minimize trade-offs between them. They also represent a major change from the Millennium Development Goals (MDGs). Not only are the SDGs universal and challenging all countries, they also offer a broad sustainability agenda, giving equal attention to social, economic and environmental issues; by contrast, the MDGs had a greater focus on the social agenda, paying insufficient attention to economic and environment issues. Thus, the environment is incorporated into the SDGs more extensively than it was into the MDGs (UNEP 2016c).

Furthermore, where the MDGs mainly aimed at poverty reduction in developing countries (with developed countries committing to a Global Partnership for Development), the 2030 Agenda is a universal one, with goals and targets to be achieved by all countries. According to UNEA, the 2030 Agenda “represents a paradigm shift to replace today’s growth-based economic model with a new model that aims to achieve sustainable and equitable economies and societies worldwide” (UNEA 2016 p.1), noting that “ecosystems and the services they provide, such as food, water, disease management, climate regulation, and spiritual fulfilment are preconditions” for sustainable development, while “unsustainable patterns of production and consumption threaten our ability to achieve sustainable development”.

The environment is represented in all the SDGs. More than half have a direct environmental focus or address the sustainable use of natural resources (UNEP 2016d). Many goals are directly related to the quality of the physical environment, e.g. water (SDG 6), climate (SDG 13), oceans (SDG 14) and land and biodiversity (SDG 15). Other goals are more indirectly related to the physical environment, e.g. via natural disasters (SDGs 1 and 11), food, hunger and agriculture (SDG 2), human health (SDG 3), energy (SDG 7), economic growth and employment (SDG 8), industry (SDG 9) and cities (SDG 11) (International Resource Panel 2014; International Resource Panel 2015; OECD 2015; Lucas *et al.* 2016). For example, SDG 8 emphasizes sustainable economic growth and decent jobs, while one of its targets calls for decoupling economic growth from environmental degradation and improving global resource efficiency in consumption. SDG 12 on sustainable consumption and production, SDG 16 on peace, justice and strong institutions, and SDG 17 on means of implementation are cross-cutting goals that support all other goals and their environmental dimensions. Clearly, the SDGs cannot be achieved without fundamental environmental progress. This is recognized in the 2030 Agenda, which directly calls for an integrated approach to sustainable development (International Resource Panel 2015).

Although the SDGs link the environment much more closely to other development areas, they do not comprehensively represent the global environmental agenda (Wackernagel, Hanscom and Lin 2017). Some important environmental problems are not well reflected in the SDGs, such as mining and natural resource extraction, and the links between gender and the environment (e.g. indoor air pollution from cooking; Elder and Zusman 2016). The climate goal (SDG 13) does not have a target or indicator directly related to the state of the climate, although it references the Paris Agreement, which does have such a target. Moreover, the environmental indicators are not as well developed as those for other areas, and there is less data available to quantify their impacts and/or progress towards achieving the related targets. Many targets have several dimensions, and often the dimension related to the environment is not included in the indicator(s). The SDGs address the goals of many MEAs, although few of the many IAEs are directly mentioned in the SDGs.

Similarly to the SDGs, other major recent United Nations agreements and frameworks, such as the Paris Agreement on climate change, the Sendai Framework for Disaster Risk Reduction and the New Urban Agenda - Habitat III, require substantial contributions from all sectors and actors, as well as significant transformation of economic and social practices. Thus, like the SDGs, these agreements have a broad scope and should be implemented using an integrated approach.

Similarly, major non-United Nations global forums (e.g. the Group of Twenty [G20], the Group of Seven [G7] and the World Economic Forum) focus increasingly on environmental issues and associated risks, especially in relation to the SDGs. In 2015, the leaders and heads of states of the G7 met in Elmau, Germany, and agreed to decarbonize the world economy by the end of this century (G7 2015); at the Ise-Shima Summit in Japan, 2016, the G7 agreed to make concerted efforts to fulfil their SDG and Paris Agreement commitments. At the Taormina Summit in 2017 in Italy, all the G7 members reaffirmed their strong commitment to swiftly implement the Paris Agreement

(except the United States of America, which was in the process of reviewing its related policies). The G7 has been holding environment ministers' meetings regularly. The G20 also adopted an SDG Action Plan (G20 2016).

Other major meetings of environment ministers include the BRICS (Brazil, Russian Federation, India, China, South Africa), the Asia-Pacific Ministerial Summit on the Environment, the African Ministerial Conference on the Environment, and the Tripartite Environment Ministers Meeting among China, Japan and the Republic of Korea. The SDGs provide a framework and common language to bring all these agreements and actions together.

The target and indicator-based approach, which was a key innovation of the MDGs, was also used by the SDGs, as well as by the Strategic Plan for Biodiversity 2011-2020, including the Aichi Biodiversity Targets developed under the CBD (Kanie and Biermann eds. 2017). Many felt that this approach made an important contribution to the MDGs' relative success in mobilizing action and support, although it also has some disadvantages (Fukuda-Parr, Yamin and Greenstein 2014). If this approach is implemented broadly in line with the spirit and language of the SDGs, and not in a narrow instrumental manner, then implementation and accountability may be strengthened (Biermann, Kanie and Kim 2017). Another major innovation for the SDGs and the Paris Agreement is that each country agreed to translate the global goals and targets into national targets and indicators; however, this will introduce the challenge/opportunity of accounting for progress.

Therefore, it is very important for GEO-6 to continue to focus global attention on MEAs, IAEs and its new focus on SDGs and non-United Nations global forums. Still, implementation of some traditional MEAs may also benefit from a more integrated approach, possibly through greater linkages with the SDGs.

One of the main tasks of GEO-6 is to assess progress on the Internationally Agreed Environmental Goals (IAEG) that have been established by MEAs, highlighting gaps between the commitments and achievements of these agreements. More importantly, it will help to inform the global response and institutional capacity-building needed to address the increasing complexity and uncertainties associated with environmental problems and addressing them through global development. Given the urgency of the challenges associated with environment and development, and the limited financial and human resources available to address them, GEO-6 is focused on a holistic and integrated approach to assessment in order to leverage synergies across issues and minimize trade-offs, and to communicate the resulting knowledge.

## 1.6 GEO-6 in the context of other environmental assessments

To address environmental challenges effectively, their wider impacts on people, economies, societies, markets, institutions, justice, security and culture must be well understood. The GEO-6 process recognizes a need for participatory and integrated environmental assessments (IEAs), and for institutionalized tools and platforms to empower people, organizations and decision makers by co-developing information and relevant knowledge on the state and trends of the environment to inform policy action and adequate responses (UNEP 2015).

GEO-6 is part of the growing body of global environmental assessments (Mitchell *et al.* 2006; Kowarsch *et al.* 2014; Jabbour and Flachsland 2017; Kowarsch *et al.* 2017). Some of these assessments are, or include, regional assessments (e.g. the European Environment Agency's State of the Environment Report) or country-level assessments, while others focus on specific themes, such as the Global Gender Environment Outlook (UNEP 2016e). These assessments are typically conducted by international organizations and programmes, like UNEP through its Environment Under Review sub-programme (UNEP 2018) and create the needed evidence base that brings clarity and transparency to the main concerns facing the planet and humanity. This evidence base includes successes and failures in addressing these issues and, most importantly, provides options for actions to make sure that current and anticipated problems are equitably and effectively addressed. This action-oriented and stakeholder-focused approach has the desired attributes of incorporating feedback from decision makers into the knowledge development process and shortening the time for implementing the information and knowledge. Annex 1-2 lists the IEAs from which GEO-6 draws.

An IEA (such as GEO assessments) follows a common methodology and procedures to ensure the consistent application

of relevant quality standards, and links science to policy by:

- ❖ analysing and synthesizing existing environmental, social and economic data to determine the state of the environment using the Drivers, Pressures, State, Impact, Response (DPSIR) framework, taking into account all ecosystem components and processes (**see Figure 1.2**);
- ❖ determining risk and uncertainty in the information;
- ❖ identifying and assessing past and potential policy and management actions;
- ❖ providing guidance for decision makers on the consequences of various policy and management actions, including not taking any action (UNEP 2017b).

## 1.7 GEO-6 approach, theory of change and structure

### 1.7.1 Approach

Historically, the GEO process was established as part of the follow up to the adoption of Agenda 21 in 1992, with the aim of placing the status of the environment under permanent review (UNEP 1995 - UNEP Governing Council in its decision 18/27). Since the first GEO in 1997, its approach and structure have undergone several changes and improvements.

**Figure 1.2: The DPSIR approach used in GEO-6**

In 1995, UNEP adopted the DPSIR causal framework approach for the GEO assessments. This represents a systems-analysis view in which the driving forces of social and economic development exert pressures on the environment, which change the state of the environment. The changing state of the environment leads to impacts on, for example, human well-being and ecosystem health, which then produces human responses to remedy these impacts, such as social controls, redirecting investments, and/or policies and political interventions to influence human activity. Finally, these responses influence the state of the environment, either directly or indirectly, through the driving forces or the pressures. Existing policies increasingly need to be assessed in terms of how they address the drivers and impacts of environmental challenges.

## Box 1.2: Multidimensional aspects of the analysis

GEO assessments are multidimensional in scope, in an effort to incorporate environmental, social, economic, policy, geographic and temporal perspectives to form various threads of evidence to answer the overarching questions. The main approaches used in GEO-6 include the following.

- ❖ The 'Healthy Planet, Healthy People' theme emphasizes the foundational importance of healthy ecosystems and environment for human health. Human health is systematically covered throughout GEO-6 by focusing on the many direct and indirect health-related impacts (e.g. diseases, mortality) deriving from environmental change and deterioration (see Chapters 2 and 4). In addition, health-related objectives are recognized within transformative environmental policies and pathways (Part B). Where possible, health-related impacts are analysed related to social criteria such as age and gender.
- ❖ GEO-6 includes thematic dimensions that track the state and trends of air, fresh water, oceans, land and biodiversity, and constitute a 'state of the environment' report (Part A).
- ❖ GEO-6 presents more than 25 policy case studies that highlight the importance of evidence-based policymaking (Chapters 12-16). The case studies allow examination of how to design effective policies without being policy prescriptive.
- ❖ GEO-6 includes cross-cutting dimensions that combine social, economic and environmental aspects of complex challenges. GEO-6 covers 12 cross-cutting issues (e.g. food, energy, resource use, gender, health, disasters, etc.) throughout the assessment of the environmental themes (Chapter 4) and policy effectiveness (Chapter 17), adding a specific focus on the interlinkages between the environmental and other dimensions of the 2030 Agenda/SDGs.
- ❖ For the first time, GEO-6 examines climate change as both a driver (i.e. built-in climate change) and a cross-cutting issue (i.e. anticipated impacts) in the sustainable development context through its overarching relevance to all other aspects of GEO-6 (Chapters 2 and 4).
- ❖ GEO-6 considers the equity dimension systematically by considering distributional, representational and procedural issues in the various parts of the assessment, highlighting impacts and possible opportunities of environmental policies and future development pathways to overcome inequities.
- ❖ The outlook chapters of GEO-6 (Part C) combine traditional global and scenario-based analysis with local, participative and decision-based analysis. This aims to provide a solution-oriented perspective which considers relevance and efficacy.
- ❖ GEO-6 uses modern tools and platforms (e.g. crowdsourcing) to expand stakeholder engagement in the assessment process (Chapter 23).

Based on the core principles of developing integrated environmental assessments (UNEP 2017b), the scope of the GEO has evolved. A key new feature of GEO-6 is increased emphasis on the interactions and interlinkages between the environment and human health. The changing approach and structure of this GEO reflects the most recent scientific evidence and the new geopolitical context, particularly implementation of the 2030 Agenda. GEO-6 provides the evidence base for addressing the environmental dimension of the SDGs.

The GEO-6 process in itself is part of the effort to strengthen overall capacity-building within the global environmental governance system, in order to increase the level of science-based decision-making on multiple levels (United Nations General Assembly Resolution 2997 of 1972). The GEO is an independent, expert-led, participatory process created to facilitate the interaction between scientific understanding and policy development. Policymakers, as well as a wide range of scientists and stakeholders, are consulted on each edition's focus and methodology through the High-Level Intergovernmental and Stakeholder Advisory Group, the Scientific Advisory Panel and the Assessment Methodologies, Data and Information Group, which provide advice and guidance throughout the GEO process. This participatory and consultative process gives GEO assessments scientific credibility, accuracy and authority, as well as policy relevance.

In addition to producing GEOs, UNEP has a mandate for capacity-building. This is an integral part of the GEO process and works at different levels, using various mechanisms. GEO reports include contributions from leading international experts

from a wide range of organizations worldwide, as well as a team of GEO Fellows who are early-career professionals or students.

The thematic dimensions (state and trends of air, fresh water, oceans, land and biodiversity) were also core elements of previous GEOs, but all the other approaches listed above are new to GEO-6.

Annex 1-3 contains information on the theory of change that GEO-6 is built upon, and Annex 1-4 provides information on how the authors of each chapter have established confidence statements for the main findings of each chapter. These confidence statements can be found in the Executive Summaries for each chapter and are expected to assist policymakers in understanding the extent of the evidence that exists on a subject, and how much of that evidence is in agreement on the findings presented in this assessment.

### 1.7.2 Structure

Based on this mandate and scope, the contents of GEO-6 are structured as shown in **Figure 1.3**.

Three chapters complement this introduction, Chapter 2: Drivers of Environmental Change, Chapter 3: The State of Our Data and Knowledge, and Chapter 4: Cross-cutting Issues. As information and data become more important in society, knowledge creation and use also become even more important within GEO-6, since the organization of data, information and knowledge form the foundation of scientifically sound assessments and informed policy decision-making. Therefore,

Figure 1.3: Structure of GEO-6, with a link to its Theory of Change (see Annex 1-3)

GEO-6 makes greater efforts to explain both changing needs and new opportunities around data, information and knowledge generation derived from UNEP's mandate to deliver the environmental dimension of the SDGs.

The global human system has many deep-rooted path dependencies, which have evolved over a long time. As society and civilization have evolved and dynamic, the interlinkages between human and environmental systems have become more complex and dynamic. To understand the most relevant structural elements of the human system, GEO-6 systematically examines the overall drivers, for example, population and demographic changes, including the causes of migration, current economic trends and technological developments.

One new element is Chapter 4 on cross-cutting issues, which presents the evidence explaining how the state and trends of the environment are already impacting human systems on various scales. The twelve cross-cutting issues addressed in GEO-6 are also important SDG issues: health, environmental disasters, gender, education, urbanization, climate change, polar regions and mountains, chemicals, waste and wastewater, resource use, energy and food systems). GEO-6 uses a matrix-approach to address these cross-cutting issues,

considering each within the context of the five environmental themes (air, biodiversity, oceans, land, fresh water). This approach helps reflect the growing need to synthesize more effectively our knowledge on the environment's multidimensional functionality and how it already affects human systems.

The analysis in GEO-6 is divided into four parts:

**Part A: State of the Global Environment** features five thematic chapters providing the latest data and information on the state and trends of air, biodiversity, oceans, land, oceans and fresh water. Chapters 5-9 have a common structure using the DPSIR approach, and each includes information on related policy responses.

**Part B: Policies, Goals, Objectives and Environmental Governance, an assessment of their effectiveness** evaluates the effectiveness of the current policy landscape within the existing environmental governance structure at multiple scales, based on the policy responses identified in the thematic chapters in Part A, including the cross-cutting issues (Chapters 10-17). The methodology developed for this assessment is based on a combined top-down and bottom-up approach. The results are used to extract guidance for policymakers and to support the promising policy approaches addressed in the final

section of the report. Based on this analysis, Part B also identifies needs for further improvements to the global environmental governance system (Chapter 18).

### **Part C: Outlooks and Pathways to a Healthy Planet with Healthy People**

incorporates the most promising policy approaches from Part B into the pathways of transformation. It combines global and scenario-based analysis (Chapters 20-22) with local, participative analysis (Chapter 23) to identify possible pathways towards achieving the environmental dimension of the SDGs and other MEAs (up to 2030), and assesses long-term or mid-century strategies required for achieving long-term sustainability (to 2050) (Chapter 24). The outcomes and conclusions provide a baseline to guide policymaking and implementation of the SDGs, as well as the development of more transformative pathways to reach scientific targets over a longer time-horizon (to 2050), such as the objective to become a climate-neutral, resource-efficient society. This long-term perspective will help to guide the further development of global, regional and national governance

systems to ensure future human development stays within the Earth's ecological limits, and helps to create a more equitable world with no one left behind. Where possible, Part C emphasizes the economic and social costs and benefits of various options for action and non-action.

**Part D: Remaining Data and Knowledge Gaps** (Chapter 25) provides an overview of the data/knowledge trends and issues and identifies the gaps that need to be filled in order to implement the SDGs and achieve the IAEs established in MEAs. This is based on the premise that more data/knowledge leads to better and more effective actions/solutions in more places. A revolution in communications and information technology is creating significant new data and information opportunities beyond traditional environmental monitoring and assessment.

We hope readers – whether policymakers, researchers or citizens – find the analysis and assessment findings presented in the following chapters useful, helping to inform future efforts to address our collective environmental challenges.

# Chapter 2

## Drivers of Environmental Change

**Coordinating Lead Authors:** Tariq Banuri (University of Utah), Fernando Filgueira Prates (Centro de Informaciones y Estudios del Uruguay (CIESU)), Diego Martino (AAE Asesoramiento Ambiental Estratégico and ORT University), Indu K Murthy (Indian Institute of Science), Jacob Park (Green Mountain College), Dimitri Alexis Zenghelis (London School of Economics)

**Contributing Author:** Matthew Kosko (University of Utah)

**GEO Fellow:** Maria Jesus Iraola Trambauer (University College London)

# Executive summary

**Population growth will be highest in countries that are very poor, have a low carbon footprint per capita and high gender inequity in terms of access to education, work, and sexual and reproductive rights** (*well established*)<sup>1</sup>. It will also remain important in countries going through their early or late demographic dividend (most middle-income and upper middle-income countries). These are also the countries that have presented the highest increases in carbon footprints per capita – and in ecological footprints more broadly. {2.3.1}<sup>2</sup>

**The world's population will become older, including in the global South, more urban and will live in smaller households** (*well established*). In a business-as-usual scenario, all these trends will contribute to higher levels of emissions. This is true even if, in some cases, urban milieus show a more efficient relationship between welfare improvement and environmental footprint. {2.3.3}

**Between today and 2050, the global urban population will continue to increase** (*well established*). Around 90 per cent of the growth of cities will take place in low-income countries, mainly in Asia and Africa, which are the world's most rapidly urbanizing regions. {2.4}

**Serious social and environmental challenges of urbanization remain unsolved in many urban areas, particularly but not solely, in the global South** (*well established*). These challenges can be exacerbated by climate change and rapid urban growth in regions and cities that currently lack the capacity to face these mounting pressures. {2.4.1, 2.4.2}

**On the other hand, urban population growth can represent an opportunity to increase citizens' well-being while decreasing their ecological footprint** (*established but incomplete*). Urbanizing areas can therefore be seen as an opportunity for the reduction of greenhouse gas (GHG) emissions through the appropriate planning and design of urban form and infrastructure. {2.4.4}

**Economic development in the past has been a driver of increased resource use and environmental damage** (*well established*). The production of internationally traded goods accounts for about 30 per cent of all CO<sub>2</sub> emissions. The household consumption, meanwhile, of goods and services over their life cycle, accounts for about 60 per cent of the total environmental impact from consumption (UNEP 2010). Economic development continues to be the number-one policy priority in most countries, because of its material benefits and its potentials for poverty eradication, for narrowing inequalities in income and wealth between and within countries, and for providing win-win scenarios that can facilitate collective action and global solidarity. At the same time, economic development must coincide with sustainable consumption and production. {2.5.1, 2.5.4}

**Achieving the SDGs will require that the fruits of sustainable economic development are predominantly used to increase the capacity, capabilities and opportunities of the least-advantaged people in societies** (*well established*). Educating girls, improving the status and opportunities for women, and enabling poor people to achieve full participation in society will strengthen both sustainable economic growth and sustainable economic development, and reduce alienation and conflicts in society. {2.5.2, 2.5.3}

**Technological advances have resulted in both positive as well as negative impacts** (*well established*). Oil and other fossil fuels have accelerated economic development and lifted the standard of living for billions of people in both industrialized and developing countries, but they have also contributed to climate change. At the same time, there are current and emerging technology business models, which are building a more circular economy, creating less resource-intensive processes, and accelerating more effective resource innovation cycles. {2.6.1, 2.6.2}

**Technological advances have created unintended consequences that make it difficult to determine whether the advances have long-term positive and/or negative impacts** (*established but incomplete*). Scientific analyses of technology issues often fail to capture the important negative and rebound effects of technologies as well as the complex policy and market challenge of diffusing sustainable technologies to developing countries. {2.6.3, 2.6.4}

**Climate change has become an independent driver of environmental change and poses a serious challenge to future economic development** (*well established*). Regardless of human action, or even human presence on the planet, impacts will continue to occur. Climate change thus poses a challenge to growth and development. {2.7.1, 2.7.2}

**Climate change poses risks to human societies through impacts on food, and water security** (*established but incomplete*), and on human security, health, livelihoods and infrastructure. These risks are greatest for people dependent on natural resource sectors, such as coastal, agricultural, pastoral and forest communities; and those experiencing multiple forms of inequality, marginalization and poverty are most exposed to the impacts. {2.7.3}

**Climate change will amplify existing risks and create new risks for natural and human systems** (*well established*). Risks are unevenly distributed and are generally greater for developing countries (mainly for SIDS) and for disadvantaged people and communities in countries at all levels of development. Risk of climate-related impacts results from the interaction of climate-related hazards with the vulnerability and exposure of human and natural systems, including their resilience and ability to adapt. {2.7.4}

<sup>1</sup> This assessment uses confidence statements to better inform policy makers of the extent of evidence on a particular subject and the level of agreement across this evidence. The various confidence statements used include: "well established" (much evidence and high agreement), "unresolved" (much evidence but low agreement), "established but incomplete" (limited evidence but good agreement) and "inconclusive" (limited or no evidence and little agreement). Annex 1-4 provides more information on the use of confidence statements.

<sup>2</sup> Statements in the Executive Summaries of different chapters are referred to the subsections of the chapter where the underlying analysis and evidence for the statement can be found.

**There is an important need to limit the potential negative sustainability impacts of drivers of population, economic development and climate change** (*established but incomplete*). Whether these three drivers serve as catalysts of positive

(rather than negative) transformative response in the form of social equity, environmental resilience, and poverty eradication is likely to be determined by uncertain long-term impacts of drivers of urbanization and technology. {2.8, **Figure 2.23**}

## 2.1 Introduction and context

The environmental movement has gone through many phases. Initially the movement consisted broadly of the conservation school, which emphasized husbanding of both renewable and non-renewable resources (especially forests) for future development, and the preservation school, which saw nature as intrinsically valuable (Eckersley 1992). In addition to these economic and aesthetic concerns, the modern environmental movement is now more about risk, the risk that environmental degradation poses to human health and well-being (Carson 1962; Rees 1995; Guha 1999; Lenton *et al.* 2008; Rockstrom *et al.* 2009a; Diamond 2011). Increasingly, there are concerns that the enormous gains in life expectancy and quality of life since the industrial revolution are in danger of being reversed (GBD 2015 Mortality and Causes of Death Collaborators; Harari 2017).

The five drivers reviewed in this chapter – population growth and demographics, urbanization, economic development, new technological forces, and climate change – have led to an unprecedented expansion of wealth for many but have also left many behind and could produce trouble for the future. If current trends in inequality continue, the top 0.1 per cent of the population will own more wealth than the global middle class by 2050 (WID 2018).

### 2.1.1 Overview of the Drivers

As noted in Section 1.6, the analysis conducted in the GEO-6 uses the DPSIR framework, where DPSIR stands for Drivers, Pressure, State (of the environment), Impact (on the environment and human well-being), and Response<sup>3</sup>. ‘Drivers’ are anthropogenic *inertial* forces – social, economic, ecological, technological, and political. They are inertial forces, in the sense that they have their own rules of motion and reversing them will require time and effort. GEO-5 referred to two drivers – population and economic development – to which GEO-6 adds three more, urbanization (previously covered under population), technology and climate change.

Three of these drivers – population, economic development, and technology – are ubiquitous in the DPSIR literature (Nelson 2005) and represent the disaggregation into three components of aggregate human consumption, and therefore of what is necessary for meeting survival as well as other welfare needs.

- ❖ *Population*: Other things being equal, more people will mean a proportionally higher pressure on the environment. In such a scenario, long-term sustainability is incompatible with growing populations, which the literature indicates will continue to grow at a global scale throughout this century. It is imperative in the present, therefore, to attend to how key population dynamics – including fertility rates, ageing populations, displacement and gender inequality – interact at multiple scales and impact environmental sustainability.
- ❖ *Economic development*: This refers to an increase in human welfare, which depends on material consumption and many other factors, including the environment. While economic development has been highly correlated with economic growth in the modern era, the two are quite

distinct, empirically as well as conceptually. Per capita consumption is expected to continue increasing in the foreseeable future (because of the unfinished agenda of eradicating poverty, meeting survival needs and enabling individuals to pursue prosperity). To decouple growth from negative environmental impacts, resource-efficient, sustainable patterns of consumption are needed.

- ❖ *Technology*: Technological change is well understood as a driver of change, both negative and positive. Negatively, it provides an opportunity to accelerate, with incentives, the harnessing of natural resources for human ends; in times of crisis, incentives strongly favour adoption of riskier options and elimination or minimization of safeguards. Positively, technological progress also creates more efficient options, which can meet human needs at lower resource costs.

In this assessment, urbanization and climate change are added as independent drivers because of their importance in socioeconomic change.

Urbanization has been going on throughout history, but its pace, scale and impact have accelerated sharply in recent decades. As such, it is included independently as a fourth driver.

Likewise, climate change has been added as a fifth driver, even though, in principle it could be represented as an outcome of the other drivers. According to the Fifth Assessment Report (AR5) (Intergovernmental Panel on Climate Change [IPCC] 2014), the world is on the threshold of entering the era of ‘committed climate change’, namely that some impacts of climate change have now become irreversible (such as extinction of species and loss of biodiversity) and regardless of future mitigation or adaptation actions. In other words, even if all human activity were to cease, the impacts of climate change would continue to manifest themselves over the next few centuries.

Taken together, these five drivers are bringing about changes in natural as well as social systems. These impacts range from resource depletion to biodiversity loss, water scarcity, changes in the hydrological cycle, health impacts, and ecosystem degradation as well as pollution. In the absence of an adequate response, a changing climate could lead to a pre-modern world of famine, plague, war, and premature death.

## 2.2 Changes since the last assessment

A number of changes, summarized as follows, have taken place since the fifth Global Environmental Assessment (GEO-5).

- ❖ *Population*: With the 2018 world population estimated at 7.6 billion people, estimates by the United Nations indicate that the peak human population is likely to be higher than had been projected earlier. The world has also seen an increase in the number of migrants and refugees, in part as the result of heightened conflict and increased environmental degradation. Other demographic variables remain on track.
- ❖ *Urbanization*: Having passed the symbolic 50 per cent of population living in urban areas, trends indicate that rural-to-urban migration will continue, with acceleration in the global south. This represents both an increased driver of environmental pressure and an opportunity to enhance sustainability.

<sup>3</sup> Note that The DPSIR framework has come under some criticism, especially on the elision over the interdependence between the drivers. In this assessment, we include an explicit examination of this interaction.

- ❖ *Economic development*: The global economy is coming through a slow recovery from the 2008 recession, and there are concerns about the persistent debt crisis, the increase in income inequality, and emerging instability due to trade wars. Offsetting factors include the increasing role and contribution of emerging economies, and the adoption of the Sustainable Development Goals (SDGs) as a new global aspiration and orientation for development (Section 2.5.1).
- ❖ *Technology*: The environmental crisis is creating perverse incentives for countries and businesses to resort to environmentally riskier technological options, including geo-engineering and nuclear technology. Yet it is also providing sound incentives for such technologies as renewable energy, energy efficiency, energy storage, and expanded application of information and communications technologies (ICTs).
- ❖ *Climate change*: The IPCC-AR5 states that 'the warming of the climate system is unequivocal, as evidenced by observations of increases in global temperatures, widespread melting of snow and ice and rising sea level'. IPCC also notes that human influence on the climate system is clear, and that 'many aspects of climate change and associated impacts will continue for centuries, even if anthropogenic emissions of greenhouse gases are stopped' (IPCC 2014, p. 16).

Besides the drivers themselves, various policy developments since GEO-5 also need mention. A number of global agreements were reached to address key issues pertinent to this assessment, including a new comprehensive treaty to address climate change, an agreement on the new development agenda, including the adoption of the SDGs, and agreements on mobilization of finance for development as well as climate action. In addition, several countries adopted national policies on disaster risk management, renewable energy, urbanization, transport, and water and sanitation.

Recent years have also seen increased interest in technologies that can accelerate social and environmental benefits and enable people, institutions, and communities to achieve their needs at lower resource costs. Section 2.7 focuses on the interactions across the five selected drivers and how actions on one driver may affect the others.

## 2.3 Population

Rapid population growth can undermine economic development at the national level and is associated at the local level with lower status and opportunities for women (Casey and Galor 2017; Kleven and Landais 2017). Other things being equal, a larger population means higher consumption, which in the long run puts increased pressure on natural resources. This is in spite of the fact that the short-run effect of a higher population growth rate does not imply a higher growth rate of consumption or resource use.

### Box 2.1: Relationship between higher population and growth rate of consumption and resource use

Countries with higher population growth rates are typically also poorer, have lower carbon footprints per capita and experience slower growths in income per capita. For this reason, increased population does not always lead to increased consumption or resource use. High inequality and population growth are also inextricably linked. Inequality is a root cause of both rapid population growth and environmental degradation. To moderate population growth in high-growth regions, people need access to voluntary family planning and other reproductive health services, as well as to educational and employment opportunities.

While the most important source of environmental pressure comes from the global North and its high carbon footprint per capita, high population growth in the global South is expected to – under current conditions – reinforce environmental pressures and enhance global inequality. Here, countries are transitioning to early and late demographic dividend stages.

Equally, high population growth rates constitute a drag on the development process. Whereas most countries that have been able to make the transition to developed status have seen massive reduction in their fertility rates (Sinding 2009), at the level of families and individuals, poverty, conversely, is typically associated with having many children (Gillespie *et al.* 2007).

### Box 2.2: The demographic dividend

The demographic dividend takes place when the dependency ratio goes down – because of lower fertility and the fact that societies have not aged yet. Post-dividend societies are those that are already starting to increase their dependency ratio, led now by older people. Countries going through their demographic dividend – also called the window of demographic opportunity – benefit from increasing numbers of active-age population (15-64 years), decreasing numbers of young dependents (0-14 years) and small numbers of older people (64 years and over). In schematic terms, pre-dividend countries are the poorest, early dividend ones are the low- to middle-income countries, and late demographic dividend countries are mostly upper middle-income countries. Post-dividend countries are almost always rich countries with some upper middle-income countries from the former socialist block. Pre-dividend countries and those in early stages of the demographic dividend are expected to increase their population quite strongly, late-dividend societies are expected to grow still, but more moderately, and post-dividend societies will increase their populations in the years to come at a much slower rate or, in some cases, might even decrease their absolute population, and will continue to increase their older population. Pre-dividend countries and those in early stages of the demographic dividend have a smaller carbon footprint per capita and GDP. Yet as can be seen in this chapter, both early- and late-dividend countries (where both population and GDP should be expected to grow) have increased their carbon footprint per capita substantially.

Figure 2.1: World population, emissions and fertility

Source: Own elaboration based on World Development Indicators (2017 (<https://data.worldbank.org/products/wdi>))

Finally, countries with high population growth rates are often characterized by adverse conditions for women, including lack of access to education and health services, lower levels of literacy and life expectancy, higher rates of maternal and child mortality, significant barriers to participation in the labour force, and other discriminatory factors (Iversen and Rosenbluth 2010).

Sexual and reproductive health is often thought of as a universal right. While no single human right is framed in such terms, in the words of the United Nations Population Fund [UNFPA], “no country today – even those considered the wealthiest and most developed – can claim to be fully inclusive, where all people have equal opportunities and protections, and fully enjoy their human rights” [UNFPA 2017, p. 10.] Not only are sexual and reproductive inequalities and economic inequality strongly correlated, but the literature demonstrates they may be mutually reinforcing (UNFPA 2017). Poor women, particularly those who are less educated and live in rural areas, are often least able to access sexual and reproductive health services. Lack of access to these services, including contraception, places a woman at heightened risk of unintended pregnancy, which results in greater health risks and lifelong negative economic repercussions for herself and her children (UNFPA 2017).

Population growth can affect the environment not only through consumption and use of natural resources, but also through its impact on other factors. This includes the strain it can create on governance, its effects on the probability of conflict over limited resources, and its impact on rapid and unplanned urbanization (Organization for Economic Cooperation and Development [OECD] 2016).

As an example, consider the experience of Latin America. As one of the regions with the highest inequalities, it experienced rapid urbanization and the formation of megacities far too rapidly for governing systems to cope. The result was inequality within dysfunctional urban milieus, rendering them segregated, unsafe and violent, in turn starving them of public resources, dampening economic growth, shrinking civic spaces, weakening public and merit goods, and undermining the quality and availability of collective services (Filgueira 2014). This reinforces inequality by encouraging private, segregated solutions for leisure, education, security, transport and housing.

The following analysis focuses on global population trends and global effects on environmental sustainability with some discussion of impacts on a subregional, national and local level.

The expected trends show that global population growth rates will slow but will continue to be positive in all regions except Europe, at least until 2040 – even in the most conservative estimates (United Nations Department of Economic and Social Affairs [UN DESA] 2017). This means that population growth will remain quite strong in many developing regions. These regions will also rapidly increase gross domestic product (GDP) and consumption per capita given both historical trends and accepted projections. The rapid increase in the carbon footprint per capita of countries sitting in the middle of the demographic transition (early- and late-demographic dividend) clearly illustrates the likely effects of high population growth on CO<sub>2</sub> aggregate emissions under current circumstances (Figure 2.2).

Migration will probably move a large part of the population born in areas of low carbon footprint per capita (rural areas, the

**Figure 2.2: Emissions per capita according to demographics**

Source: Own elaboration based on World Development Indicators (2017) (<https://data.worldbank.org/products/wdi>)

global South) to areas of higher carbon footprint (O'Neill *et al.* 2012; OECD 2016). These are shifts that can increase the efficiency of carbon production per unit of output (technology or agglomeration reduces pressure for a given level of welfare). These shifts also increase consumption, however, and so increase aggregate CO<sub>2</sub> emissions in the process.

Finally, the still-growing world population will become older and is living and will live in smaller households (Dalton *et al.* 2008; O'Neill *et al.* 2012; UN DESA 2017).

These trends imply – on average, and again, with other things being equal – a higher carbon footprint per capita. In most cases, this simplified logic of population growth, dynamics and growing carbon emissions (assuming a business-as-usual scenario – see Chapter 21) also applies to the national and local levels and to other environmental variables such as water and air pollution, soil degradation, desertification and deforestation.

It should be stressed that population dynamics and population growth do not in themselves lead to an unsustainable environmental path. Rather, this path is the result of population growth happening with the current consumption and production patterns. Unsustainable consumption and production are each largely fuelled by heightened inequality. Both within and between countries, inequality remains one of the largest obstacles to environmental sustainability (Chancel and Piketty 2015; Oxfam 2015).

There are two detrimental effects against sustainability that are produced directly by heightened inequality:

1. because of the highly uneven distribution of resources, the level of growth required to lift people out of poverty is far larger than it would be in a more egalitarian distribution (Ravallion 2001; Bourguignon 2002; World Bank Group 2004). Put another way, the world would not have to grow at very high rates to improve the lives of those worse off if the distribution of those gains was more equally distributed.

2. high inequality is associated with a preference for overconsumption of private and positional goods, weakening public and merit goods (López and Palacios 2014; Samaniego *et al.* 2014).

Because public and merit goods usually mean collective consumption and lower marginal costs per unit consumed, because they are built on with economies of scale, they are far more efficient than private and positional goods in terms of their environmental footprint needed for their production and consumption. In particular, as societies become more urban, there is a unique opportunity for expanding collective goods (both public and merit goods) such as public transport, common utilities, green public spaces for recreation, bike lanes for mobility, and collective food preparation in full-time schools and work environments (Samaniego *et al.* 2014). A collective meal, a bus, a bike or a public park has the potential to satisfy needs (mobility, food, leisure) with a significantly lower footprint than private cars, individual food preparation, or an enclosed shopping mall (Jorgenson *et al.* 2015). Yet high inequality leads precisely to a preference for the private goods and services and not the former, because of fear, fragmentation, status competition and segregation.

It is because of the inevitability of population growth and other demographic dynamics (urbanization, smaller households and ageing populations) that it is critical to decouple these trends from unsustainable environmental pressure, by changing current consumption and production patterns.

### 2.3.1 Global population growth and composition

Four trends can be predicted with confidence: the world population will continue to grow (until at least 2050; **Figure 2.3**), average age will increase, populations will become more urban, and household sizes will become smaller (United Nations 2015a). These trends are the inevitable results of underlying processes: industrialization, the agricultural technological revolution and resulting landholding patterns, the shift from extended households towards nuclear ones, and the dramatic drop in mortality due to the epidemiological transition (Lopez and Murray 1996; GBD 2015 Mortality and Causes of Death Collaborators 2016).

Policy and behavioural changes could moderate the rate at which these changes occur, but not reverse them. All other things being equal, smaller households, urbanization and ageing will generate more environmental impact per capita. Given that such trends are inevitable – to a larger or lesser extent – there are only three possible courses of action.

1. when possible and desirable, such trends can be moderated. For example, lower fertility (due to improved access to contraception and improved economic and social empowerment for women) is positive for economic development, moderating inequality, combating poverty and decreasing environmental pressure.
2. avoiding rapid surges in unplanned urbanization due to expulsion from rural areas provides a win-win scenario,

allowing for national trajectories and urbanization processes that are more balanced and welfare-enhancing, which could enhance green cities and improve ecosystem connectivity. (rural expulsion is due in part to underinvestment in sustainable farming techniques and overexploitation in the depletion of natural resources, among other causes.)

3. patterns of consumption and production remain highly inefficient in terms of CO<sub>2</sub> production and other environmental pressures. Both hard and soft technological innovations (substitutes for fossil fuel energy sources, soil management, urban planning, collective care services in urban centres, public transportation, etc.) can drastically change the elasticity of consumption and production to units of environmental pressure.

### 2.3.2 Population growth estimates

In 2017 (UN DESA 2015a), the total world population was 7.55 billion, growing at 1.10 per cent annually, a decline from a decade earlier, when it was growing at 1.24 per cent. Under middle projections for fertility, there will be 8.55 billion people by 2030, and almost 10 billion by 2050 (9.77 billion). However, any forecast looking a century into the future comes with significant caveats. Depending on the rate of decline in fertility rates, the global population could rise as high as 13.2 billion by the end of this century or reach 9.4 billion by mid-century and stay around those levels until 2100 (see Section 21.3.1).

**Figure 2.3: Projected world population**

Source: United Nations Population Fund (2017)

**Figure 2.4: Consumption and associated environmental pressures are unequally distributed between nations**

Note: In order to better represent the contribution of different groups of emitters to total CO<sub>2</sub> emissions, the charts split the world in three groups: top 10 per cent, middle 40 per cent and bottom 50 per cent CO<sub>2</sub> emitters in each country. For each of these groups, the chart presents the percentage of the group's emissions stemming from each region of the world.

Source: Chancel and Picketty 2015.

The key points to take away from this projection are:

- that the population will continue to rise until at least the middle of the century, and perhaps longer,
- that there are significant uncertainties about long-term trends, and
- that population control is not responsive to direct policy intervention, but rather indirectly to policies that, for example, lower fertility rates through women's control over reproductive choices.

Population growth depends on the numbers of births and deaths in a given year, and these in turn depend on three interrelated factors – fertility, mortality and the age and sex structure of the population. These last three depend on human behaviour, health conditions and demographic inertia, respectively. While age and sex structures change slowly, there are uncertainties about the rate of decline of fertility rates, as well as future trends in mortality rates. Also, while changes in fertile behaviour result in a lower rate of population growth, they do so only eventually, after considerable lags.

Mortality rates are declining rapidly in almost all developing countries, but fertility rates remain high in the least developed group, where the average is above 4 children per woman, almost twice the replacement level of fertility of 2.1 children (UNFPA 2017). Fertility rates can respond to gender policies, but if emerging medical technologies result in a dramatic extension of lifespans, population growth would be closer to the higher-end estimates, and ageing of the world population would be far more pronounced.

### 2.3.3 Population composition and distribution

There is increasing evidence of the complex interactions between the environment and the distribution and composition of the population (age, urban/rural residence, and household structure) (see Jiang and O'Neill 2007; Dalton *et al.* 2008; O'Neill *et al.* 2012; Liddle 2014).

Population growth is distributed unevenly around the globe and within nations, as a result of differences in fertility patterns and migration trends. Countries with high fertility rates, young populations and steeply declining mortality rates will grow more rapidly than others. In the coming decades

(Figure 2.5), According to current trends Africa is projected to grow the fastest, followed by Asia, Latin America, North America, Oceania and Europe (United Nations 2015b, 2017).

The impact of natural population growth is partially mitigated by migratory patterns, which will lead to shifts in population from less developed regions to more developed ones, and from rural to urban areas (OECD 2016). The pace of migration has increased in the last 50 years and will continue to do so in the next 30 years (Massey and Taylor 2004; International Organization for Migration [IOM] 2015). This is driven by the persistence of the underlying push-and-pull causal factors:

- ❖ the push effects of global inequality, poverty, conflict-ridden regions, and
- ❖ the pull effects, such as already established migrant communities in more developed regions sometimes attracting others from less developed regions.

South-South international migration has also increased along the same patterns as South-to-North migration (Hujo and Piper 2010). In many cases, migration is actually fuelled by environmental degradation that makes life unsustainable in the original locations (Leighton 2006).

Migration tends to dampen population growth, as data show that migrants typically have lower fertility rates in their new contexts (Majelantle and Navaneetham 2013). The net impact on the environment can still be adverse, however, given that migrants access higher levels of income and consumption than they had in their previous milieux. Given that one of the objectives of development, as well as of migration, is less poverty, increased income and consumption are desirable outcomes.

**Figure 2.5: World population distribution and composition**

Source: United Nations Population Fund (2017)

Increased per capita consumption of resources may not be the only impact of migration on the environment and natural resources; resource efficiency may also change – for example, energy and materials use per unit of consumption may decline.

### 2.3.4 From population programmes to gender equality and women's empowerment

Population programmes, which were a major policy focus in the 1960s and 1970s, have since been discontinued in many countries, even though their benefits are widely recognized (UNFPA 2017). Part of the explanation for their decline was the systematic violation of basic rights that some of these programmes entailed through mass sterilization or forced and coercive policies limiting women's reproductive choices.

**Figure 2.6: Contraceptive prevalence and total fertility**

Source: Own elaboration based on World Development Indicators (2017) (<https://data.worldbank.org/products/wdi>)

The United Nations International Conference on Population and Development in Cairo in 1994 and the Women's Conference in Beijing in 1995 contributed to the view that population policies should respect the rights of women and their choices, moving from population targets to a rights-based approach that places reproductive control in the hands of women. There is little doubt that existing population policies in Africa, Asia and parts of Latin America can contribute markedly to moderating the rate of population growth while respecting gender equality and empowering women. In turn, this seems likely to contribute to more robust economic growth, through higher female labour-force participation in the market economy, and improved health for mothers as well as children (UNFPA 2017).

These policies comprise a suite of actions, including access to modern contraceptive methods (Figure 2.6), improved access for women and men to voluntary family planning and other reproductive health services, investment in women's education, removal of barriers to female labour-force participation, institution of legal penalties for discriminatory practices associated with traditional patriarchal behaviour, and investment in the social and economic uplift of less developed areas within countries, and of developing countries more generally.

### 2.3.5 Gender and education

Placing reproductive choices as much as possible in the hands of women has proven to have a definite impact on timing and quantity of childbearing (UNFPA 2017; United Nations Entity for Gender Equality and the Empowerment of Women [UN Women] 2017). This is affected, in part, by access to education and employment. One of the main contributing factors to high fertility rates is lack of women's access to education and employment opportunities. In least developed countries, where fertility rates are highest, access to education for girls tends to be lowest. Causal relations run both ways. (Figure 2.7).

**Figure 2.7: Female secondary education and total fertility rates**

Source: Earth Policy Institute (2011)

### 2.3.6 Inequality, migration and cities

North-South inequality and international inequality in general is a major driver of migratory patterns. Closing international welfare gaps and promoting growth in the South has proven to help moderate migratory flows, which can allow for slower and eventually less CO<sub>2</sub> intensive welfare enhancing trajectories.

Similarly, within-country migration is driven by inequalities, especially between rural and urban areas, leading to rapid – and sometimes environmentally unmanageable – urbanization. Again, adequate developmental support for rural areas helps moderate such pressures. (IOM 2015).<sup>4</sup>

## 2.4 Urbanization

A distinct channel through which demographic trends affect environmental resources is through urbanization (also analysed as a cross-cutting issue in Section 4.2.5 of this report). The facts about urbanization are well known. Urban areas have higher incomes and consumption, greater access to political power, higher rates of economic growth, and, per capita, place a higher pressure on natural resources. On the other hand, cities exhibit greater efficiency in the use of resources per unit of income generated and better potential for energy efficiency (Dodman 2009; Bettencourt and West 2010; Barrera, Carreón and de Boer 2018; Cottineau *et al.* 2018). Cities are also the engines of economic growth. No country has made the transition from

poverty to middle-income status without experiencing a period of rapid urbanization. Managed effectively, though, urbanization can help in the achievement of SDGs, efficiently and sustainably. Finally, urbanization is generally associated with a lowering of fertility rates (Martine, Alves and Cavenaghi 2013).

Slightly more than half of the world's population is currently living in urban areas, a share that is expected to rise to 60 per cent by 2030 and 66.4 per cent by 2050 (Brenner and Schmid 2014; United Nations 2014; Melchiorri *et al.* 2018). It should be noted that urban areas are defined in different ways worldwide, so UN DESA information is based on heterogeneous data sources. Using a globally harmonized definition of urban areas that combines demographic characteristics and density grids, Melchiorri *et al.* (2018) place global urban population at 85 per cent in 2015. Alternative understandings of the urban condition (Brenner and Schmid 2014) that can benefit from these new methodologies, and from an analysis of the transboundary ramifications of cities (Section 4.2.5), could represent an important tool for policy analysis and environmental governance.

Around 90 per cent of the growth of cities will take place in low-income countries (United Nations Human Settlements Programme [UN-Habitat] 2014). Africa is the world's most rapidly urbanizing region, while European cities grew the least in the 1995-2015 period (UN-Habitat 2016). The critical factor accounting for these trends is neither fertility nor age structure (which are, respectively, lower and older in urban areas), but migration (UN-Habitat 2016).

The coming decades are crucial. It took 200 years for the urban share of the world's population to rise from 3 per cent to 50 per cent, to 3.5 billion people in 2010 (United Nations 2014). This population is set to more than double over this century, but in all the centuries that follow, we may add, at most, another billion or so. This makes the current global urbanization era not just immense, but also brief (Fuller and Romer 2014). The choices around investment and design of new and existing cities are effectively determining the infrastructure, technologies, institutions and patterns of behaviour that will define the functioning of our cities and the future of the planet for the foreseeable future. This suggests there is a very narrow window of opportunity to help plan and design this future. The world's infrastructure will more than double in the next 20 years (Bhattacharya *et al.* 2016).

### 2.4.1 Cities of different sizes face different challenges

The pattern of urbanization is also relevant for understanding both the potential for growth and the impact on natural resources. At the high end of urbanization are megacities, defined by UN-Habitat as cities with more than 10 million people (UN-Habitat 2016, p. 7), most of which are located in the global South. In 1990, there were 10 megacities housing 153 million people, or 7 per cent of the total urban population; by 2014, there were 28 megacities, with 453 million people, or 12 per cent of the total (UN DESA 2014); in 2016 there were 31 megacities, 24 located in the less developed regions or the global South; of these, 6 were in China and 5 in India (UN DESA, Population Division 2016).

<sup>4</sup> This support in rural areas is not an alternative to avoiding migration. Such a policy can still have detrimental effects on migrants and host areas.

However, while megacities might be economic powerhouses, they do not represent the majority of the urban population (see Figure 2.8), and are not the fastest-growing urban centres (see Figure 2.9). Small and medium cities now account for roughly 50 per cent of the world's urban population and are growing at the fastest rates (UN DESA 2014; United Nations Economic and Social Commission for Asia and the Pacific [UNESCAP] and UN-Habitat 2015). They will "deliver nearly 40 per cent of global growth by 2025, more than the entire developed world and emerging market megacities combined" (UN-Habitat 2015a, p. 2; Dobbs *et al.* 2011). Small and medium cities are also

more vulnerable to natural hazards than big cities and megacities (Birkmann *et al.* 2016).

#### 2.4.2 Urban agglomeration economies

Agglomeration economies reflect the advantage of people clustering to reduce transport costs for goods, people and ideas. Higher productivity attracts inflows of people, who in turn further increase productivity. Agglomeration economies thus generate a positive feedback loop and multiply the impact of external productivity factors, and so boost urban populations and wages (Glaeser and Gottlieb 2009; Zenghelis 2017).

Figure 2.8: Global urban population growth propelled by cities

Source: United Nations (2014, p. 13)

Figure 2.9: City growth rates

Source: Birkmann *et al.* (2016)

Cities are a source of wealth creation, where wealth is measured as the sum of natural, human, and physical assets (Hamilton and Hartwick 2017). Natural capital includes land, parks, green spaces, water and biodiversity. Human capital includes the population's education, knowledge and skills. Physical (or manufactured) capital includes such things as housing, infrastructure, industry and offices. Added to these is intangible capital – ideas and inspiration captured in forms that include research and development, patents, intellectual property rights, customer lists, brand equity, social capital and institutional governance. Intangible capital is perhaps the most important but feeds off and interacts with the other forms of capital. It also provides the source for innovation and investment necessary to decouple growth from resource use and CO<sub>2</sub> emissions, in absolute levels as well as in rate of growth terms.

A growing body of research supports the hypothesis that cities have the capacity to spread knowledge, so the key driver of wealth is now the ability to attract skilled and creative individuals and to nurture and spread ideas. Cities therefore appear to have a comparative advantage in more idea-intensive sectors. Unlike manufacturing, which is increasingly located outside cities, ideas-oriented industries tend to cluster in urban centres. It is unsurprising that much of the generation and distribution of ideas occurs in major cities given the role of close spatial proximity. The evidence clearly suggests that the direction of innovation is strongly influenced by urban and national planning and policy, and there is substantial scope for policy to direct cities towards resource-efficient low-carbon innovation.

Urbanization carries its own penalties of success, including pollution, congestion, urban heat effect, ill health, crime, informal settlements (slums), lack of affordability and waste. Unregulated, unplanned urban sprawl might appear to be the cheapest option in the short run, as it requires minimal institutional interference, infrastructure provision and urban

planning. But the medium- and long-run costs to society, the economy and the environment can be dire. Unregulated cities will be less attractive, more polluted, congested and inefficient in the use of resources. About a third of the global urban population lives in slum-like conditions without basic services and social protection (United Nations Population Fund 2010/2011 cited in Urban Habitat III #1, p.3). Poor women living in slums are particularly vulnerable and face barriers to accessing some of the advantages of urban living (United Nations Population Fund 2014 cited in Urban Habitat III #1, p.2). Moreover, two thirds of urban dwellers live in cities where income inequalities increased between 1980 and 2010 (Lopez Moreno 2012 cited in Urban Habitat III #1 p.1). Urban sprawl, poor public transport and a lack of access to basic services such as water, waste collection and energy offset the economic benefits of urban concentrations and increase costs. These growth penalties hinder opportunities to prosper and also exacerbate urban poverty. Unplanned urban growth also leads to excessive GHG emissions, alienation and social exclusion, as well as a range of other social, economic and environmental costs such as congestion, ill health and crime (Floater and Rode 2014).

These trends place an enormous burden on governance structures (Frank and Martinez-Vazquez 2014; UNESCO and UN-Habitat 2015). In developing countries, local taxes, measured as a percentage of GDP, are three times lower than in industrialized countries (Bird and Bahl 2008).

Similarly, many of the small and medium-sized cities “lack the technical capacity to lead a major urban development process” (UN-Habitat 2012, p. XIV) and suffer from devolved responsibilities without corresponding resources, hampering their planning capacity (Frank and Martinez-Vazquez 2014). The result is that the capacity of urban governments to protect both natural resources and the rights of its citizens is severely circumscribed.

Mass urbanization is not new in Europe, North America and richer parts of Asia, but the most recent wave is focused in developing regions, including Southern Asia and sub-Saharan Africa. This influx of people into cities can place great strain on urban institutional resources and infrastructure in growing cities. **Figure 2.10** shows that in countries with lower levels of urbanization and higher growth, urban citizens are highly vulnerable – vulnerability being “calculated by adding the urban susceptibility, the lack of coping capacities and the lack of urban adaptive capacities” (Garschagen *et al.* 2014, p. 46). If the relative change in the degree of urbanization is disaggregated by income class for the 1990–2015 period, it can be seen that in Asia, low-income countries (LICs) are urbanizing at the fastest rates (15.5 per cent) in comparison with low to middle-income countries (LMCs), at 1.2 per cent, and upper middle-income countries (UMCs), at 1.5 per cent. A similar pattern is seen in Africa – where the urbanization rates are 8 per cent for LICs, 3.6 per cent for LMCs and 5.7 per cent for UMCs – and in Latin America and the Caribbean. Globally, the

pace of change in urbanization overall is 2.3 per cent (1990–2015), and the disaggregation by income class reveals the pace of change in LICs is 8 per cent while in LMCs it is 1.6 per cent (Melchiorri *et al.* 2018)

These rapidly urbanizing areas present a challenge but also represent “the largest opportunities for future urban GHG emissions reduction [... because their ...] urban form and infrastructure is not locked-in” (Seto *et al.* 2014, p. 928). As is presented below and in Part B of this report, there are positive and negative examples of rapidly urbanizing areas with regard to environmental effects. Cities exemplify the reality emphasized in this report, that when it comes to the creation of complex spatial networks, the future is not ‘God-given’, but is system and path-dependent. If new cities are built over the next two or three decades on a resource-hungry, carbon-intensive model, based on sprawling urbanization, all hope of meeting ambitious resource and climate-risk targets will be lost. This could leave cities and countries struggling to meet their

**Figure 2.10: Where rapid growth faces high vulnerability**

| Classes of urban vulnerability | Level of urbanization | Growth rate 2000–2015 |
|--------------------------------|-----------------------|-----------------------|
| ● Very low                     | 75.80                 | 0.71                  |
| ● Low                          | 69.19                 | 0.92                  |
| ● Medium                       | 56.07                 | 2.36                  |
| ● High                         | 43.51                 | 2.89                  |
| ● Very high                    | 38.59                 | 3.71                  |

Source: Garschagen *et al.* (2014)

resource needs and unable to compete in global markets, with the stranding of physical and human assets. Cities are also vulnerable to environmental and climate impacts such as heat, water stress, and floods; while coastal cities face sea level rise, saltwater incursion and storm surges.

### 2.4.3 Trends in urban expansion and density

Currently there are different views regarding territorial expansion of cities and population growth. In the absence of sustainable urban management, some studies show that cities are growing in size more than in population, reporting territorial expansion at double the population growth (Angel *et al.* 2011). Pesaresi *et al.* (2016) show that between 1975 and 2015, built-up areas increased 2.5 times while total population increased by a factor of 1.8 (Figure 2.11), with the highest

urban growth concentrated in India, China and countries in Africa. Urban land growth in these regions has also outpaced urban population growth rates, suggesting that urbanization has resulted in sprawled developments (Seto *et al.* 2011; Wolf, Haase and Haase 2018). Even in cities that are shrinking in population, sprawl still occurs (Schmidt 2011; Wolf, Haase and Haase 2018). Conversely, recent studies from Asia have shown that urban population has grown faster than urban land (in eastern South-East Asia, a 31 per cent population increase compares with a 22 per cent land increase) and that urban areas (in East Asia) are four times more dense than in land-rich developed countries: two times more than in Europe, 1.5 times more than in the Latin American and Caribbean region, and 1.3 times more dense than in the Middle East (Schneider *et al.* 2015; World Bank Group 2015).

Figure 2.11: Built-up area vs. Population (1975-2015)

Source: Pesaresi *et al.* 2016

Increasing density alone is insufficient to make the transition to sustainable cities. Another factor that affects urban impact on the environment is urban form, namely the pattern of urban physical infrastructure, which cannot be easily modified, and determines land use, transportation and energy demand for long periods of time (Seto *et al.* 2016; Güneralp *et al.* 2017). Form patterns have implications for energy consumption, GHG emissions, biodiversity (Seto, Güneralp and Hutya 2012; Salat, Chen and Liu 2014), water infrastructure (Farmani and Butler 2014) and land use and conversion of croplands (Bren d'Amour *et al.* 2016). Urban form, "infrastructure design and socio-spatial disparities within cities are emerging as critical determinants of human health and well-being" (Ramaswami *et al.* 2016, p. 940).

#### 2.4.4 Urbanization as an opportunity

In a world where environmental limits are visibly closer, and with rural to urban migration expected to continue, urban population growth can represent an opportunity to increase citizens' well-being while decreasing their ecological footprint. This is made possible through lifestyle choices, improved governance, awareness and education programmes, the availability of infrastructure and services, and technological solutions. Small and medium cities have a particularly important role to play as they are usually a stepping stone between rural populations and urban centres (UN-Habitat 2015c, p. 3). In other words, urbanization can be positive, but will only amplify existing challenges if poorly managed. If cities could build technological solutions that took advantage of economies of scale not feasible in rural contexts, they could potentially hold the promise of limiting the negative environmental effects of population growth and increased consumption.

### 2.5 Economic development

The term economic development has been used in the literature to distinguish it from a one-dimensional measure of human welfare, which focused solely on economic growth (or, properly speaking, the growth in GDP). It includes, for example, social equity, poverty eradication, the meeting of basic human needs (access to health, education, and water and sanitation services), the provision of physical infrastructure (housing, energy, transport and communications), and the guarantee of essential political, economic, and social freedoms as elaborated by Sen (2011). Similarly, the term economic development highlights structural transformation, namely the changes in industrial structure (from an agriculture-based structure towards industry and services), social organization (from small-scale productive activities towards large-scale organizational structures), and the diversification of skills. The SDGs are derived from this broader concept of economic development.

#### 2.5.1 The social role of economic growth

As the economy has moved from an 'empty world' to a 'full world' (Daly 1973), it has become clear that conventional growth cannot continue far into the future (United Nations Environment Programme [UNEP] 2011). Yet the social and political commitment to a vision of unending growth remains as strong as ever. The reasons are easy to see. Economic

growth plays a number of vital roles in modern society, including poverty eradication, the pursuit of social justice, the building of social solidarity, the defence of civic peace and the establishment of good governance.

The most important of these is poverty eradication. Two and a half centuries after the advent of the Industrial Revolution, about 783 million people (10.7 per cent of the global population), still live on less than US\$1.90 per day, and 48.7 per cent of the population lives on less than US\$5.50 per day (World Bank Group 2013). Globally, about 22 per cent of children are stunted and 7.5 per cent are underweight (UNICEF 2018a) while 264 million children and adolescents are unable to enter or complete school (UNICEF 2018b), the majority of them girls. Nearly 2.1 billion lack access to safely managed water and 2.3 billion lack basic sanitation (UNICEF/WHO 2017).

This poverty is not because of a lack of economic resources. In 2017, the world's average income per capita was \$16,906 per year (PPP, current international \$), which is \$46 per day (World Bank Group 2018) and about 24 times the poverty threshold. While redistributive policies and social security arrangements can help people to cope with poverty, the only reliable mechanism for eradicating poverty is to enable the poor to benefit from fast, steady growth.

Another argument for economic growth in developing countries is the need to narrow the huge income gap that separates them from developed countries. Indeed, this gap continued to widen well into the second half of the 20th century. Only in the 21st century was there evidence of a narrowing of the gap, as growth rates in developing countries began to outstrip those in developed countries (Figure 2.12).<sup>5</sup>

As such, even critics of the growth agenda agree that it is essential for developing countries (see, e.g. Jackson 2009, p. 4). Their main critique focuses on developed countries, where growth is, they argue, neither necessary nor desirable (see Daly 1973; Rees 1995; Victor 2008; Jackson 2009). Others (e.g. Friedman 2005) argue, however, that growth continues to play important political roles in developed countries, including supporting fairness, social mobility and social solidarity, while attracting popular support for civic and international peace (Benhabib and Rustichini 1996, p. 139; Weede 1996, p. 32; Gartzke 2007, p. 180).

In sum, then, the recent episodes of global economic growth are associated with:

- a. a narrowing of the income gap between developed and developing countries, and
- b. a huge dent in the incidence of poverty in the latter countries.

The danger is that if the growth engine slows down, these trends may not continue, and this could – as outlined in the report of the United Nations Secretary-General on climate

<sup>5</sup> This was in large part due to the higher growth rate in the large populous economies, especially China and India, but was not restricted to them. Indeed, the first decade of this century witnessed the first occasion when sub-Saharan developing countries, as a group, grew by more than 5 per cent per year for 5 years. However, the global financial crisis has resulted in the slowing of average developing country growth rates by 2-3 per cent, and a widening in the variance in growth rates, as larger countries (e.g., Brazil, China, Germany and the United States) recovered more quickly than smaller economies.

Figure 2.12: How growth rates in developing countries began outstripping those in developed countries

Source: Canuto (2010)

change and its possible security implications (A/64/350) – signal a reversion to a zero-sum world in which conflict and war would proliferate, governance systems atrophy and popular support diminish for social justice, solidarity and civic peace.

The question is not whether growth in developed countries is needed to meet their material aspirations, but whether it is an essential element in the quest of modern societies to meet their political, social, cultural and even moral and ethical goals. Ideally, economic growth and environmental sustainability are mutually reinforcing rather than in conflict.

### 2.5.2 From growth to development

Economic growth is only one of the factors contributing to human welfare, which also depends on social justice, poverty eradication, good governance (including anti-corruption efforts) and environmental health. The global policy process has sought to reflect this integrated approach in the form of the Millennium Development Goals (MDGs) and SDGs.

The structure of the SDGs provides an insight into the broader issues discussed in this section. The MDGs were motivated by a simple idea, namely the resolve of heads of state and government at the Millennium Summit of the United Nations General Assembly to halve poverty in 15 years (United Nations, 2000). The SDGs take it a step further and seek to eradicate poverty and hunger by 2030. In addition, the SDGs draw explicit attention to environmental and social factors, including climate change, terrestrial and marine biodiversity, sustainable consumption and production, inequality, industrialization

and decent jobs, and peace and justice (United Nations Development Programme [UNDP] 2018).

In retrospect, the MDGs were a qualified success; they coincided with accelerated progress on poverty eradication, health and education, but lagged on nutrition and on access to water and sanitation (McArthur and Rasmussen 2017). The successes of the MDGs can be attributed to four factors, in descending order of significance, namely: high economic growth in developing countries, support for local programmes and community-based initiatives, large vertical programmes (especially in the health sector), and the enactment of legal rights and protections. Although it is difficult to assess the causal impact of MDGs (it is impossible to know what would have happened in their absence), some empirical research has found evidence of the MDGs accelerating progress in these areas (McArthur and Rasmussen 2017).

Although the SDGs seek to build on this success, the underlying context is very different. Their adoption was preceded by a major financial crisis, barely avoiding a full-fledged financial meltdown, a long-drawn out recession in industrialized countries, a potentially disastrous debt crisis, a dramatic rise in income inequality in the OECD countries, recurrent commodity-price volatility, significant political fallout from food price shocks, shrinking natural resources and biodiversity, growing evidence of adverse climate-change impacts, an increasing awareness that the global economy was coming up against planetary boundaries (Rockström *et al.* 2009b), and a dramatic rise in global conflicts.

The SDGs can be loosely grouped into three categories:

- ❖ *Human development*: tackling income poverty, hunger, lack of access to basic services (health, education, water and sanitation) and gender inequality (i.e. SDGs 1-6),
- ❖ *Economic development*: enabling conditions for poverty eradication, providing access to energy, providing economic growth, decent jobs, infrastructure and industry, declining inequality, housing, and peaceful societies (SDGs 7-11 and 16-17)
- ❖ *Environment*: ensuring that the agenda of poverty eradication (and by implication, of economic growth) is protected against ecological threats (SDGs 12-15).

This agenda is relevant to the Global Environment Outlook assessment. The poverty agenda remains unfinished, and the development consensus remains that its pursuit will require further economic growth in the world economy. There is a growing concern, however, that the prospects of development itself are increasingly threatened by the closing in of planetary boundaries, especially through the impacts of climate change. In the loop's other direction, there continue to be fears that the growth process entails increasing use of natural resources and sinks, thus increasing the pressure on the natural environment.

The poverty agenda remains the highest priority of the international policy community, as documented in almost every international agreement pertaining to economic development and the environment in the past quarter century. The reasons for this are not exclusively or even primarily altruistic. In the words of the founding principles of the International Labour Organization (ILO), as cited by its Director-General: "poverty anywhere is a threat to prosperity everywhere" (ILO 2011). The reasons thereby reflect an understanding that

global peace cannot be built on conditions that condemn a significant segment of humanity to permanent deprivation and subservience.

### 2.5.3 Recent experience

The financial crisis was followed by a slowdown in global growth. The reasons for this were to do with stagnant international trade, revival of the spectre of trade wars, heightened policy uncertainty, and a dampening of the main engine of global growth, namely emerging economies (World Bank Group 2017, p. 3). From an average of about 6 per cent growth per year between 1992 and 2008 (and a height of 10 per cent per year in 2006-2008), growth in global trade has shrunk to about 1 per cent since 2010 (see Figure 2.13). More recently, this appears to have resulted in renewed threats of trade wars.

A second notable trend is the rising inequality in industrialized countries. There is a paradox in the contrasting movements in international and intra-national inequality. For much of the 20th century, income inequality between countries widened (or, at best, was static), while income inequality within countries narrowed (or, at worst, remained static). Since 1980, however, both these trends have reversed.

One consequence is Milanovic's global elephant curve, so called for its shape as seen in Figure 2.14 (Lakner and Milanovic 2013, p. 31; Weldon 2016). This shows that between 1988 and 2011, while the incomes in the top 1 per cent as well as those in the 40-70 percentiles (presumed to be in developing economies) were rising, incomes in the bottom 10 per cent and in the 80-90 percentiles (presumed to be in the middle class of developed countries) were growing more slowly.

Figure 2.14: Milanovic's elephant curve

Source: Data from Lakner (2013) and artwork from da Costa (2017)

The relationship between income inequality and the use of natural resources is not straightforward. On the one hand, the classic economic argument is that the poor have a higher propensity to consume than the rich (Carroll *et al.* 2017), and transferring income from the former to the latter should therefore reduce the impact on the natural environment. On the other hand, heightened income inequality creates upward pressure on resources, both through the impact of conspicuous consumption and out of the squeezing of the middle class. More importantly, inequality has the potential to exacerbate conflict, which in turn has an adverse impact on the environment. Inequality's effects on the environment move through the consumption, investment and community channels (Islam 2015).

There are two main justifications for the global growth agenda: the material one and the political one. The former is for the role of growth in poverty eradication while the latter is for the pursuit of growth for its possible contribution to other needed political aims, such as social justice, fairness, solidarity, civic peace and democratic governance.

Recent trends show that a significant dent has been made in the twin agendas of poverty eradication and reduction of global, between-country inequality. On the other hand, the manner and pace at which this has happened has given rise to new tensions and fractures, both within and between countries.

This may indicate that there has been a renewed urgency for reviving the growth momentum, not only in developing countries, but equally in developed ones too.

#### 2.5.4 The role of energy

A key question is the relationship between two different dimensions of economic development, namely aggregate economic growth and resource consumption, especially the consumption of energy.

There is a large body of literature on decoupling economic growth from its impact on resource consumption (see, e.g. UNEP 2011; UNEP 2017; Hennicke 2014). A key distinction is between renewable and non-renewable resources. Since the latter are finite in nature, the only way to reduce depletion is to reduce, reuse and recycle (the three Rs). However, as has been noted prominently in the literature, this redirects the focus onto energy consumption (i.e. on the energy component embedded in resource use). The 3R strategies are fairly well known; their viability depends on the cost of energy used for recycling or reuse relative to the cost of new extraction.

Some renewable resources, such as solar and wind, are drawn on without concern that these resources will run out. Other resources are renewable as long as the encompassing ecosystems are not degraded. For renewable biomass

resources such as forests, the primary challenge is ensuring that their use does not exceed the rate of natural (or enhanced) regeneration. This, too, boils down to the rate with which these resources can regenerate themselves by harnessing the energy of the sun. Various techniques of increasing natural resource productivity are equivalent to enhancing their energy-harnessing potential.

In short, as noted by Hennenke (2014, p. 2), energy is the key to decoupling. Not surprisingly, environmental analysis has often used the concept of energy flows to frame these issues. Energy, construed broadly, is the motive force in both human and natural affairs. The miraculous transformation introduced by the Industrial Revolution is in essence the result of harnessing an enormous volume of readily available energy resources, namely fossil fuels (Smil 2010; Bithas and Kalimeris 2016). This is a major factor responsible for the idea of a permanently growing economy.

As we look to the future, the need for energy will continue to increase, not only to promote economic development in poor countries, but also to help reduce the unsustainable consumption of material resources. To avoid catastrophic climate change and a scarcity of resources, a major shift is needed by this increase, towards affordable and sustainable energy resources (see e.g., Yihdego, Salem and Pudza 2017; UNDP 2018, SDG 7).

## 2.6 Technology, innovation, and global sustainability

Technology can be a positive and a negative driver of environmental change. Technological innovation has been – and is likely to continue being – a critical driver of sustainability changes at a global level (Segars 2018). At the same time, technologies have often created unintended consequences that are far beyond the predictive ability of our best scientific analysis (e.g. the impact of effects of fossil fuel consumption on the climate system). Existing scientific analyses of technology issues often fail to capture the important negative/rebound effects (Chitnis *et al.* 2013) of the systematic impact of technologies as well as underplay the problem of technology diffusion, particularly in terms of agricultural technological innovation (Juma 2015). Motor vehicles and electricity are good examples of past scientific limitations. They represent two of the most important technological breakthroughs of the 20th century, but their negative environmental and resource impacts are likely to persist well through the 21st century.

### 2.6.1 Technological innovation and sustainable economic development

From an economic perspective, technological innovation has long been recognized as one of the core drivers of economic development, but in modern theories of growth it is given a pre-eminent role (see Romer 1994; Acemoglu and Daron 2009; Zenghelis 2011). Innovation in human capital, through investment in research and development and knowledge-sharing, is the key not only to productivity growth, but also to getting more out of the resources we have. This is crucial to solving many environmental problems.

Innovation offers the most important route out of many environmental problems. In an environmentally sustainable

economy, economic growth and development would still occur, and humanity would continue to prosper. Economic growth and human well-being can be decoupled from material throughput and environmental impact, though the policy challenge of actually achieving this is considerable (Jacobs 1991; Hepburn and Bowen 2013).

Recognition of new opportunities, together with the falling cost of key low-carbon technologies (solar, wind, etc.), has proved game-changing in terms of driving global policy action. While the United Nations Framework Convention on Climate Change (UNFCCC) negotiations are often seen as moving slowly, 40 countries and 20 subnational regions have implemented or are planning to implement carbon pricing and other types of low-carbon technology-enabling policies (Global Commission on the Economy and Climate 2015). There are now over 1,200 climate change or climate change-relevant laws worldwide, which is a 20-fold increase over the past 20 years (Nachmany *et al.* 2017).

The Paris Agreement on climate change (United Nations Framework Convention on Climate Change [UNFCCC] 2015) itself can be seen as a consequence of accelerating momentum in countries, cities and businesses across the world to reduce GHGs. Falling technology costs of renewables and energy efficiency, growing market opportunities, changing behaviours, and a growing awareness of the co-benefits of lower emissions (such as less urban pollution and congestion, and fiscal opportunities from pricing scarce resources, carbon and pollution and from removing environmentally damaging subsidies) all helped to support the voluntary commitments signed into action after the Paris Agreement.

### 2.6.2 Cleaner and energy-efficient technologies

Rapid advances are occurring in the market development of cleaner and energy-efficient technologies, including renewables (solar, wind, advanced biomass, etc.), storage (batteries, pumped hydro, etc.), energy efficiency (e.g. demand-side management and dematerialization), decarbonized transport options (e.g. electric vehicles). Research and development advances are also emerging for cleaner technology options (e.g. carbon, capture and storage, second- and third-generation biofuels, decentralized electricity generation at small/micro scales, self-driving vehicles) (International Energy Agency [IEA] 2016b).

In the case of renewable energy, for instance, diffusion and scale-up become both feasible and affordable worldwide. By the year 2040, renewables will constitute two-thirds of the global investment in power generation, while solar energy will become the largest source of global low-carbon capacity, fuelled by growth in China and India. In the case of the European Union, renewables are expected to account for 80 per cent of new power-generating capacity, with wind energy becoming the leading source of regional electricity after 2030 (IEA 2017b).

Regionally, in the case of sub-Saharan Africa, where there are a number of public, private and cross-sector initiatives to address energy poverty, a rapidly developing cleaner and energy-efficient technology ecosystem is incubating early-stage off-grid solar technology companies, as well as helping to accelerate the overall market dynamics of sub-Saharan African countries (Park 2016; Yihdego, Salem, and Pudza 2017).

For instance, investments in off-grid solar companies in sub-Saharan Africa and other countries went up tenfold, to more than US\$200 million between 2013 and 2016 (Bloomberg New Energy Finance 2017), although it should be stressed that this rapid growth still represents a small percentage of the investments that will be needed to make an impact on the regional energy marketplace.

Scalable solar-powered off-grid electrification solutions are important for sustainable development in many developing regions and represent a critical element in the case of the sub-Saharan Africa region (International Renewable Energy Agency [IRENA] 2013). Access to energy represents a critical economic, social and environmental issue in both industrialized and developing countries because energy access is linked to a wide range of economic and environmental benefits (IRENA 2016). Yet sub-Saharan Africa as a region consumes just 145 terawatt-hours of electricity a year – or one incandescent light bulb per person used three hours a day (Lucas 2015) – making it the most energy-poor region in the world (Park 2016).

There is substantial potential for the unit costs of resource-efficient and low-carbon technologies to continue to fall as these new technologies are developed and deployed, and as engineers learn how to connect and service them cheaply. This potential is far higher for new technologies than it is for long-established, high-carbon incumbents.<sup>6</sup> For example, price drops in renewable energy technologies have allowed new combinations of solar, wind, and energy storage to outcompete coal and gas on cost.<sup>7</sup>

Not only does the energy sector benefit from productivity improvements associated with a transition to low-carbon, there are also important economic spillovers from low-carbon innovations. Acemoglu *et al.* (2012) argue that sustainable growth can be achieved by adopting temporary policy levers such as a carbon tax that can redirect innovation towards clean inputs, while Dechezleprêtre, Martin and Mohnen (2014) conclude that economic spillovers from low-carbon innovation are consistently 40 per cent greater compared with conventional technologies, while information and communication technologies (ICTs) can, in theory, vastly increase productivity and energy efficiency, while reducing material consumption throughout the lifespan of a product (a mobile phone for instance). While ICTs may one day usher in a new era in which digital technologies play a key role in accelerating global environmental governance, it is not yet clear if the energy and materials savings are greater and outweigh the cumulative sustainability impact of the ICT product lifespan from resource extraction to waste disposal (see Box 2.3 on electronic waste).

Beyond the direct social and environmental impacts of ICTs, one emerging sustainability issue is the electricity use of data centres, which in the case of the United States is estimated to be around 2 percent of the country's total

### Box 2.3: Electronic waste

Electronic waste (e-waste) – which can be defined as “items of electrical and electronic equipment and their parts that have been discarded by the owner as waste without the intention of re-use” – represents one of the fastest-growing waste streams in the world (Solving the E-waste Problem (StEP) Initiative 2014).

Fuelled by rapid global sales of computers and electronics, combined with shortening product life cycles, 44.7 million metric tons – the equivalent of 6.1 kg per inhabitant of e-waste were generated in 2016, while the overall e-waste stream is expected to increase to 52.2 million metric tons or 6.8 kg per inhabitant by 2021 (Baldé *et al.* 2017).

Some e-waste from industrialized countries is being shipped to the developing world, “where crude and inefficient techniques are often used to extract materials and components”, a trend which is posing challenges to global sustainability governance (Baldé, Wang and Kuehr 2016).

electricity consumption (Whitney and Kennedy 2012). With energy efficiency of computers reportedly doubling every 1.5 years (Koomey *et al.* 2011), the more important long-term sustainability question may be the use and application of ICTs in avoiding future energy use and lowering climate change impact.

Digital technologies such as smart meters are projected to link more than 1 billion households and 11 billion smart appliances in interconnected electricity systems by 2040. The use of digital technology innovations will enable individual homes to determine when and how much they draw electricity from the grid. They will also enable the design of environmentally friendly demand-side responses in the building, industry and transport sectors, resulting in US\$270 billion of avoided new investments in new electricity infrastructure (IEA 2017a). Governments of cities ranging from Copenhagen to Addis Ababa are also investing in ICT-based smart technologies (e.g. open data stores, citizen engagement platforms) to help improve urban governance at lower financial and environmental cost (C40 Cities Climate Leadership Group 2015).

### 2.6.3 Food-agricultural technology

A number of global food-agricultural trends – population growth and increasing global affluence, among others – will require increased agricultural productivity (by as much as 60–120 per cent on 2005 levels), in direct conflict with the wider SDGs (Ort *et al.* 2015).

Moreover, there is a wide range of perspectives in terms of what the yield gap is likely to be – the difference between how much a crop could yield per hectare with enough water and nutrients, and how much is currently being harvested (White 2015) – and over what technology options are available to address it. Total agricultural production is projected to increase by 60 per cent by 2050 compared with 2005 (Alexandratos and Bruinsma 2012), due to an increase in global population and in the number of people from the developing world who can afford to eat more and better food. The emerging question confronting the international community is likely to be: will the global food supply be adequate to meet global food demand,

<sup>6</sup> The so-called sailing ship effect (whereby the introduction of steam ships induced a leap forward in efficiency and design of sailing ships) suggests that incumbent industries can respond with competitive innovation when faced with existential competition.

<sup>7</sup> Solar photovoltaic and onshore wind technologies are competitive with gas and coal in a number of global locations, even without a carbon price. The cost of solar photovoltaic modules fell by 60 per cent in the two years to the first half of 2017, and by a factor of five in the five years post-2008 (Bloomberg NEF 2017). Energy storage prices are falling even faster than solar photovoltaic and wind prices. A recent study found that research and development investments for energy storage projects have lowered lithium ion battery costs from US\$10,000/kWh in the early 1990s to a trajectory set to reach US\$100/kWh on or by 2018 (Kittner, Lill, and Kammen 2017).

and can this demand be met without adversely impacting land use, biodiversity, freshwater use and other natural resources? If not, can this demand be met, or reshaped, using alternative technologies beyond agriculture as we know it today?

Bijl *et al.* (2017) suggest that a sustainable balance between reducing global hunger and staying within, among others, the planetary boundaries of land and water use might be struck by changing dietary patterns and more effectively addressing food waste as a policy priority. In the case of agricultural water use, a Pacific Institute study (2014) concluded that the adoption of existing water technologies and management techniques could reduce agricultural water use in the state of California by 5.6 million to 6.6 million acre-feet (one acre-foot is 1,233.48 cubic metres) per year, or by between 17 and 22 per cent, while maintaining the same level of agricultural productivity.

The International Food Policy Research Institute (IFPRI) (2014) argues that certain agricultural technologies and practices (e.g. crop protection, drip irrigation, drought tolerance, heat tolerance, integrated soil fertility management, no-till farming, nutrient use efficiency, organic agriculture, precision agriculture [see Box 2.4], sprinkler irrigation, water harvesting, and land conservation measures) might be scaled up to achieve the dual goal of increasing food production and reducing food insecurity in the developing world. No-till farming alone can increase maize yields by 20 per cent, while heat-tolerant varieties of wheat can lead to a 17 per cent rise in crop yields (IFPRI 2014).

With the livestock sector accounting for about half of food-system GHG emissions (Food and Agricultural Organization of the United Nations [FAO] 2017; Gerber *et al.* 2013), emerging food-agricultural technologies may have the potential to reshape demand for animal produce and increase the sustainability of the food system. Reducing overall meat consumption as well as providing alternatives to conventional livestock production systems (e.g. through the introduction of plant-based meat alternatives) would, for instance, substantially reduce the agricultural land use footprint from food production (Alexander *et al.* 2017). In another example, although there are uncertainties in terms of an increased

energy-use rebound effect<sup>8</sup>, production of cultured or *in vitro* meat requires smaller quantities of agricultural inputs and land compared with raising livestock (Mattick *et al.* 2015).

Other emerging technological advances are demonstrating the potential to decouple crop production from the vulnerability of land use and climate (Gilmont *et al.* 2018). Hydroponics employ nutrient-rich water rather than soils to grow crops, and aeroponics use nutrient-dense sprays to nourish plants suspended in the air. Both techniques permit precise application of nutrients to crops grown under controlled conditions, including in land-sparing indoor vertical farms that can be located in urban and degraded environments (Eigenbrod and Gruda 2015).

As the cost of decentralized renewable energy sources falls, the constraints to the broader deployment of these technologies, including broadening them to grow staple crops, will continue to decline as the environmental benefits increase (Kalantari *et al.* 2017). To truly accelerate innovative food and agricultural technologies on the global level, particularly in the developing world, it will also be critically important to have complementary sustainable policy initiatives, such as the FAO Global Agenda for Sustainable Livestock Initiative, to diffuse both technology-based and non-technology-based sustainable food and agricultural innovations.

## 2.6.4 Technology diffusion and global sustainability

While there is strong scientific consensus on the importance of technological innovation as a driver of global sustainability change, there is far less scientific consensus in terms of two issues: first, sustainable technology diffusion – particularly in terms of the adoption and deployment of what might be described as sustainable technologies – in the developing world, and, second, how to regulate and govern new and emerging technologies in terms of global sustainability (Juma 2015). For technological diffusion, in terms of the rates of both adoption and acceleration, a good place to start might be the market development of solar, wind and other renewable energy technologies in the developing world, particularly relating to cities and urbanization (IEA 2016a).

Although renewable energy sources accounted for 70 per cent of the net increase in the global power capacity in 2017 due to the rising economic competitiveness of solar and wind energy (REN21 2018), rising energy demand, particularly in the developing world, coupled with population growth, is likely to outpace the development of economically viable and scalable renewable-based solutions without additional technology breakthroughs in the energy sector (IRENA 2017).

To provide the necessary institutional and socioeconomic conditions for technological diffusion, there is a critical need to design the appropriate innovation scale-up conditions (Rogers 2003) and to implement new public and private measures to more effectively deal with incoherent policies, misalignments in electricity markets and cumbersome and risky investment conditions (Ang, Röttgers and Burli 2017) in both industrialized and developing countries.

<sup>8</sup> The energy use rebound effect refers to the observation that people may begin to consume more energy as a result of increases in energy efficiency.

### Box 2.4: Precision agricultural technologies

The world's population is expected to reach 9 billion by 2050, while climate change and income growth will drive food demand in the coming decades. Baseline scenarios show food prices for maize, rice and wheat would significantly increase between 2005 and 2050, and the number of people at risk of hunger in the developing world would grow from 881 million in 2005 to more than a billion people by 2050 (IFPRI 2014).

While no single technology can be offered as a solution to these global agricultural and food challenges, precision agriculture (GPS-assisted, machine-to-machine solutions that combine information collected by sensors with automated management) represents one of 11 agricultural innovations, which, in aggregate, might help by 2050 to improve global crop yields by up to 67 per cent while reducing food prices by nearly half (IFPRI 2014).

In terms of technology diffusion and sustainability pathways in OECD member countries, the emerging 'industry 4.0' model is likely to have a major impact on the nexus of technology diffusion, market development and sustainability. Industry 4.0 – which can best be described as a digital industry technology platform powered by sensors, machines and information technology systems (see Figure 2.15) – is regarded by many scientists, technology experts and business executives as the fourth wave of technological advancement (Rüßmann *et al.* 2015).

While the industry 4.0 model, particularly as a technological platform, has the short-term potential to produce more efficient processes and higher-quality goods at reduced costs, the long-term social, environmental and economic impacts, particularly in terms of employment and workforce development, remain, at best, unclear. The emerging industry 4.0 model, along with artificial intelligence, additive manufacturing, the Internet of things, and other disruptive technologies, reflects a deep uncertainty that lies at the technology-sustainability nexus: how can the international community properly weigh the sustainability risks and benefits, particularly with regard to short- and long-term impacts on employment and economic development?

Despite the growing visibility of the social, environmental and economic impacts of global climate change and environmental dilemmas, slow progress on a wide range of international environmental (e.g. climate change) and social (e.g. refugees) policy negotiations has limited the scope for so-called good public policy options and tilted the governance framework towards riskier forms of technology like climate geoengineering as a policy alternative. Whether a particular

emerging technology should be adopted or actively promoted by public organizations or private companies is not the critical issue. Rather, it is how and to what degree the international community can make sure that proper oversight, monitoring and protection against the potential adverse effects are in place as we proceed with the complex task of identifying, developing and diffusing technologies that positively impact wealthier OECD as well as lesser developed countries.

## 2.7 Climate change

GEO-6 includes anthropogenic climate change as a driver of environmental change because it has acquired a momentum independent of future human activity; it is also analysed as a cross-cutting issue in Section 4.3.1 of this report.

**Figure 2.16** demonstrates the increase in CO<sub>2</sub> concentration over the industrial period, charted on the same scale as the data for the transitions in CO<sub>2</sub> concentration between the glacial and interglacial periods over the past 20,000 years. Other GHGs such as methane and nitrous oxide have also been increasing consistently over the decades, as indicated by the National Oceanic and Atmospheric Administration's greenhouse gas index and shown by Hartmann *et al.* (2013). The impact of such changes demonstrates that climate change is now a major driver of environmental change – an inexorable force that can no longer be ignored.

According to the Fifth Assessment Report of the IPCC (2014), the world has entered an era of committed climate change. The concept of climate commitment, first introduced by Ramanathan (1988), refers to changes that are already in the pipeline, regardless of any further emissions or any future change in GHG concentrations in the atmosphere. "A large fraction of anthropogenic climate change resulting from CO<sub>2</sub> emissions is irreversible on a multi-century to millennial time scale, except in the case of a large net removal of CO<sub>2</sub> from the atmosphere over a sustained period" (IPCC 2013, p. 28).

**Figure 2.15: Industry 4.0: technological transformation of future industrial production**

Source: Rüßmann *et al.* (2015)

**Figure 2.16: Mean atmospheric CO<sub>2</sub> concentration**

Source: Based on (in blue) NOAA data from <http://www.ncdc.noaa.gov/paleo/metadata/noaa-icecore-6091.html> and (in red) data provided by Pieter Tans, NOAA/ESRL ([www.esrl.noaa.gov/gmd/ccgg/trends/](http://www.esrl.noaa.gov/gmd/ccgg/trends/) and [scrippsco2.ucsd.edu/](http://scrippsco2.ucsd.edu/))

Surface temperatures will remain roughly constant at elevated levels for many centuries after a complete cessation of net anthropogenic CO<sub>2</sub> emissions. According to Mauritsen and Pincus (2017), “due to the lifetime of CO<sub>2</sub>, the thermal inertia of the oceans [Wigley 2005] and the temporary impacts of short-lived aerosols [Hare and Meinshausen 2006] and reactive greenhouse gases, the earth’s climate is not equilibrated with anthropogenic forcing. As a result, even if fossil-fuel emissions were to suddenly cease, some level of committed warming is expected, due to past emissions, as studied previously using climate models [Solomon *et al.* 2009; Gillett *et al.* 2011; Frölicher *et al.* 2014].”

Therefore, the current global temperature is controlled largely by past CO<sub>2</sub> emitted over past decades, a consequence of the inertia in the climate and carbon cycle. The climate is committed at the current concentration of GHGs. This means that climate change has now become an independent driver of environmental change. Regardless of human action, or even human presence on the planet, impacts will continue to occur through temperature change, fluctuations of precipitation, snow melt, sea level rise, drought and other climate variables, and through changes in the hydrological cycle (Salem 2011). Climate change thus poses a challenge to growth and development.

### 2.7.1 Greenhouse gas emissions and concentration

The emission trends in selected countries are illustrated in **Figure 2.17** and **Figure 2.18**. More than half of total cumulative emissions since the Industrial Revolution were emitted in

the past four decades. Cumulative CO<sub>2</sub> emissions for the period 1750-1970 (220 years) are estimated at 910 gigatons<sup>9</sup>, while those for the period 1970-2010 (just 40 years) are about 1,090 gigatons (IPCC 2014). This growth is despite the presence of a wide array of multilateral institutions as well as national policies aimed at mitigation. The 2007/2008 global economic crisis only temporarily reduced the GHG emissions growth rate, compared with the trend since 2000 (Peters *et al.* 2011).

There is an unequal distribution of GHG emissions, both in terms of individual emissions coming from varied lifestyle consumption patterns and in terms of country emissions. The richest 10 per cent of the population emits 50 per cent of total GHG emissions, while the poorest 50 per cent emit only 10 per cent (King 2015). At the same time, when the carbon budget for limiting global warming below 2°C is considered, a generational inequality arises, with future generations having a lower allowance to emit. If the current Nationally Determined Contributions (NDCs) are fully implemented, the carbon budget for limiting global warming below 2°C will be 80 per cent depleted by 2030 (UNEP 2017).

Atmospheric concentrations of GHGs have increased from around 277 parts per million (ppm) in 1750 to 403.3 ppm in 2016 (World Meteorological Organization 2016). Regional contributions to this global GHG concentration are detailed in the GEO-6 Regional Assessments (UNEP 2016). The growth in atmospheric CO<sub>2</sub> was  $6.0 \pm 0.2$  gigatons in 2016 ( $2.85 \pm 0.09$  ppm), well above the 2007-2016 average of  $4.7 \pm 0.1$  gigatons a year (Le Quéré *et al.* 2017).

**Figure 2.17: Global growth in emissions of GHGs by economic region**

<sup>9</sup> Throughout this publication the term 'ton' refers to a metric ton or 1000 kilograms

**Figure 2.18: Emission trends in different countries from 1990-2015. Orange lines highlight growth while blue ones show reductions**

Source: Le Quéré et al. (2016)

## 2.7.2 The emissions budget

Cumulative total emissions of CO<sub>2</sub> and the response of the global mean surface temperature are approximately linearly related. Any given level of warming is associated with a range of cumulative CO<sub>2</sub> emissions. Therefore, a given temperature target (e.g. 2°C) will translate into a long-term emissions budget. Using this information, in the synthesis report of the Fifth Assessment, the IPCC (2014) estimated how much CO<sub>2</sub> we could emit and yet keep the global average temperature rise over pre-industrial levels to no more than 1.5°C, 2°C or even 3°C, which could be catastrophic.

The Paris Agreement's central aim is to strengthen a global response to the threat of climate change by keeping a global

temperature rise this century well below 2°C above pre-industrial levels, and to pursue efforts to limit the temperature increase even further, to 1.5°C (UNFCCC 2015). To accomplish this, countries have submitted NDCs outlining their post-2020 climate action, which will undergo a global stocktake every five years to assess the collective progress and to inform further individual actions by parties (UNFCCC 2015).

In order to achieve the Paris temperature target, the carbon budget that remains after deducting past emissions is between 150 and 1,050 gigatons CO<sub>2</sub>. At the current annual emission rates, the lower limit of this range will be crossed in four years and the midpoint (600 gigatons CO<sub>2</sub>) in 15 years (Figure 2.19). The emissions would have to drop to zero almost immediately after the budget is exhausted (Figueres et al. 2017).

**Figure 2.19: The carbon crunch**

Source: Figueres et al. (2017, p. 595)

If the emission pledges in the Paris Agreement are fulfilled, the worst effects of climate change can be avoided, and studies suggest this could avoid a temperature increase of 3°C by 2100 (Le Quéré *et al.* 2016). The implications of the 2017 withdrawal of the United States, the second-largest emitter, from the Paris Agreement are mixed, because the withdrawal does not preclude individual American states' policies to support environmentally friendly innovation. It is still possible to meet the Paris temperature goals if global emissions begin to fall by 2020 (Figueres *et al.* 2017).

Under current and planned policies, the world would exhaust its energy-related carbon budget (CO<sub>2</sub>) in under 20 years to keep the global temperature rise to well below 2°C. To meet the below 2°C goal, immediate action is crucial to reduce further cumulative emissions by 470 gigatons by 2050, compared with current and planned policy targets (IRENA, 2018)

### 2.7.3 Impacts of Climate Change

Climate change will amplify existing risks and create new risks for natural and human systems (IPCC 2014). The risks are not only unevenly distributed but are generally greater for disadvantaged people and communities. This is so in countries at all levels of development. The risk of climate-related impacts is a result of complex interactions between climate-related hazards and the vulnerability, exposure and adaptive capacity of human and natural systems. The rise in the rates and magnitudes of warming and other changes in the climate system, accompanied by ocean acidification, increase the risk of severe, pervasive and in some cases irreversible detrimental impacts. Already, the annual global mean surface temperature has increased at an average rate of 0.07°C per decade since 1880 and at an average rate of 0.17°C per decade since 1970 (National Oceanic and Atmospheric Administration

[NOAA] 2015). The trends in sea surface temperature, marine air temperature, sea level, tropospheric temperature, ocean heat content and specific humidity are similar (IPCC 2014) (Figure 2.20).

Beyond temperature increase, the impacts already observed include changes in the water cycle, warming of the oceans, shrinking of the Arctic ice cover, increase in the global mean sea level, and altering of the carbon and biogeochemical cycles (see more detail in Chapters 4 and 5). Further, there have been increases in the frequency and intensity of wildfires that in turn release GHGs. Observations and climate model simulations indicate polar warming amplification resulting from various feedbacks in the climate system – the positive ice-albedo feedback being the strongest (Taylor *et al.* 2013). The reduced extent of ice cover reveals a darker surface, which leads to a decreased albedo, in turn resulting in a stronger absorption of solar radiation and a further acceleration of warming. In response to the increased warming in the Arctic, sea-ice extent is strongly decreasing, especially in summer (Vaughan *et al.* 2013). However, recent literature has concluded that temperature feedbacks play a dominant role, making surface albedo feedback the second main contributor to Arctic amplification (Pithan and Mauritsen 2014).

The global water cycle has been affected, impacting on global-scale precipitation patterns over land, and on surface and subsurface ocean salinity, contributing to global-scale changes in frequency and intensity of daily temperature extremes since the mid-20th century. The global mean sea level rose by 0.19 metres (range, 0.17-0.21 metres) over the period 1901-2010, calculated using the mean rate over these 110 years, and based on tide gauge records plus, since 1993, satellite data (IPCC 2014).

Figure 2.20: Multiple independent indicators of a changing global climate

Source: IPCC (2014)

Changes in the climate system have had large-scale impacts on various ecosystems, as documented across the thematic chapters that follow in Part A. As a driver of environmental change, climate change is exacerbating current pressures on land, water, biodiversity and ecosystems. If atmospheric CO<sub>2</sub> concentration increases from the current levels of 406 ppm to 450-600 ppm, leading to greater than 2°C warming over the coming century, it will lead to several irreversible impacts, including sea level rise (Smith *et al.* 2011). O'Neill *et al.* (2017) have elaborated individual risks as well as overarching key risks, including risks to biodiversity, health, agriculture and so on, as well as risks of extreme events such as extreme precipitation and heat waves and risks to specific ecosystems such as mountain and Arctic, to name but a few (see Figure 2.21).

Future climate will thus depend on the combination of committed warming caused by past anthropogenic emissions, the impact of future anthropogenic emissions, natural climate variability and climate sensitivity. There are regions (particularly at northern, mid- and high latitudes) already experiencing greater warming than the global average, with mean temperature rise exceeding 1.5°C in these regions.

These impacts have implications for the quality and quantity of ecosystem services, as well as for patterns of resource use, their distribution and access across regions and within countries.

Time is running out to prevent the irreversible and dangerous impacts of climate change. Unless GHG emissions are reduced radically, the world remains on a course to exceed the agreed temperature threshold of 2°C above pre-industrial levels, which would increase the risk of pervasive effects of climate change, beyond what is already seen. These effects include extreme events (including flooding, hurricanes and cyclones) leading to loss of lives and livelihoods, pervasive droughts leading to loss of agricultural productivity and food insecurity, severe heat waves, changes in disease vectors resulting in increases in morbidity and mortality, slowdowns in economic growth, and increased potentials for violent conflict (Salem 2011; SIDA 2018). The extent, distribution and acute nature of the impacts is different between countries, and several islands have faced multiple impacts in one season – Haiti in 2004, for example – or annually in multiple years, such as Dominica experiencing hurricanes Erika in 2015 and Maria in 2017. These impacts can undermine food security mechanisms and systems, as well as social and economic progress in health and other areas.

Figure 2.21: The enhanced burning embers diagram, providing a global perspective on climate-related risks

Source: O'Neill *et al.* (2017, p. 30)

Figure 2.22: Trends in numbers of loss-relevant natural events

Source: Munich Re (2017)

One indication of the potential impacts is the doubling of the frequency of climate-related loss events (**Figure 2.22**) since 1980 (Hoeppe 2016). These events are already estimated to have resulted in the loss of 400,000 lives and the imposition of a cost of US\$1.2 trillion annually on the global economy, wiping 1.6 per cent from global GDP.

These risks are greatest – currently as well as in the future – for people who are dependent on natural-resource sectors. Such people include coastal communities, people in agricultural and forest communities, and those experiencing multiple forms of inequality, marginalization and poverty, thereby amplifying existing risks and create new ones for natural and human systems. The scale of potential damage from climate change poses a major systemic risk to our future well-being and the ecosystems on which we depend, in particular for societies in less-developed, less-resilient countries (OECD 2017).

#### 2.7.4 Implications

The Paris Agreement recognizes that limiting warming by the end of the century could help prevent more problems. It explicitly states the need for achieving a balance of emissions and removals in the second half of the century. The 2°C target is important to achieve, to reduce the likelihood of more intense storms, longer droughts, rising sea levels and other natural disasters that are being increasingly reported (Munich Re 2016). To keep a good chance of staying below 2°C, and at manageable costs, emissions should drop by 40-70 per cent globally between 2010 and 2050, falling to zero by 2100 (IPCC 2014; Kroeze and Pulles 2015). The current trajectory of global annual and cumulative emissions of GHGs is inconsistent with the widely discussed goals of limiting global warming to 1.5-2.0°C above pre-industrial levels. Should emissions continue to rise beyond 2020, or

even remain level, the temperature goals set in Paris become almost unattainable. Delayed action or weak near-term policies increase the mitigation challenges in the long-term. There are risks associated with exceeding 1.5°C global warming by the end of the century (increases in the severity of projected impacts and in the adaptation needs), making the achievement of many SDGs much more difficult. The overall costs and risks of climate change include a prediction that some regions could see growth decline by as much as 6 per cent of GDP by 2050, according to a recent report from the World Bank Group (2016) on climate change, water and the economy. If the worst of the climate change-related risks are to be avoided, the pace and scale of the required economic transformation is unprecedented (OECD 2017).

## 2.8 Unravelling drivers and their interactions

The same driver of environmental change can exert both positive and negative forces on the environment, as described in the previous sections. Moreover, the five drivers highlighted in this chapter are mutually interdependent, and this interdependence can itself also be positive or negative. The cumulative effect the drivers can have on the environment has been extensively discussed in the literature (Wu *et al.* 2017).

**Table 2.1** presents the interactions between the drivers covered in this chapter. These are first-order interactions (excluding interactions with other variables) at a global scale and under current conditions.

The aggregate effects of these interactions on climate change are negative. This is clear from the current trajectory of GHG emissions, which not only continue to increase, but at a rate that has accelerated in the last 15 years, compared with the 1980-2000 trajectory (Section 2.7). Thus, there is little

**Table 2.1: Interrelationships between the drivers**

|                      | Population growth                                                                                         | Economic growth                                                           | Technological change                                                                                                                                                                 | Climate change                                                                                               | Urbanization                                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Population growth    | —                                                                                                         | Negative impact due to delay in the demographic window of opportunity     | Population growth fosters technological innovation, to accommodate the additional demands. Alternatively, it could lead to lower savings and investment due to high dependency rates | Population growth increases environmental pressure, and climate change                                       | Increased pressure on urban areas, more people might move to urban areas                                                                                                   |
| Economic growth      | Higher GDP and development in general is associated with lower fertility rates                            | —                                                                         | Economic growth is associated with increased investment and technological innovation                                                                                                 | Increased economic output is associated with increased environmental pressure                                | Growth will push towards increased urbanization                                                                                                                            |
| Technological change | Technological innovation is associated with increased capacity to lower fertility rates                   | Innovation is associated with increased growth in GDP                     | —                                                                                                                                                                                    | Current trends show an increase in green technological innovation, thus lowering pressure per unit of output | Technological change can contribute to processes of urbanization or it can help to decrease the migration patterns through better access to technologies and communication |
| Climate change       | Climate change increases mortality rates and negatively affects health                                    | There are costs associated with climate change that limit economic growth | Climate change pressures foster adaptive technological innovation                                                                                                                    | —                                                                                                            | Effects of climate change on rural communities puts pressure on migration towards urban areas                                                                              |
| Urbanization         | Urbanization is associated with lower fertility rates (due to access to better health care and education) | Urbanization is strongly associated with higher economic output           | Urbanization will lead to intensification of technology use due to greater population density                                                                                        | There is no clear causal link, but there is an association between urbanization and higher emissions         | —                                                                                                                                                                          |

doubt about the unsustainability of the current interaction and aggregated effects of population growth, economic development and technological innovation.

These aggregated effects are not the same for different regions. In developed countries (such as Canada, European Union countries, Japan and the United States of America), emissions have plateaued and in some cases diminished substantially. Moderate growth, stable populations, some change in consumption patterns, and technological innovations have allowed for a reduction in aggregate GHG emissions. At the same time, emerging economies that are moving from lower middle-income status to upper middle-income status have increased aggregate emissions (this is the case in most middle-income countries, including China and India).

On the other hand, both in per-capita terms and in aggregate, it is the richest and better off countries that contribute, by far, the most to emissions. This is true both for countries by income level (the developed world accounts for more than half of total emissions, with a far higher carbon footprint per capita) or for individuals by income level within countries (people in the world's richest quintiles, both from developed and developing countries, produce both higher carbon footprints per capita and greater aggregate emissions). Consumption patterns

and production functions in the developed world, and the lifestyle and consumption options of the world's elites and better-off, therefore have to change drastically to adjust GHG emissions for a more sustainable path. The pathway to growth in emerging economies cannot reiterate the carbon expansion and GHG emissions witnessed in the last 20 years. Both technology and urbanization provide a window of opportunity – but no guarantee – for emerging economies to follow a developmental path that will prove more sustainable, from both consumption and production perspectives.

The diagram below (**Figure 2.23**) shows another way to look at the interactions between the drivers, by focusing on how each domain relates to the other, and how that can change. The diagram is used to evaluate the obstacles that different paths will confront. Three of the drivers considered – economic growth, population growth and climate change – stand at the left, while the right of the diagram presents the desired or preferred outcomes – lower environmental pressure, human well-being and equity. In the middle are the mediating

factors of technological change and urbanization (potentially enabling mechanisms, but also potentially negative forces). Economic growth, population growth and climate change are to the left because they reflect the fundamental realities of human aspiration, demographic momentum and climate change commitment. What can change the impacts of these processes is the nature of the two other drivers in the middle – technology and urbanization.

Limiting the negative effects of the various drivers described – and indeed reframing them as the catalysts of an urgently needed transformative response – is necessary to achieve sustainable development and equity, including poverty eradication. At the same time, it is important to ensure that efforts to address one driver do not undermine actions overall to promote sustainable development.

The chapters in Parts B, C and D present a comprehensive assessment that looks at development pathways more broadly, along with their policy implications.

**Figure 2.23: Relationship across the drivers**

## Box 2.5: IPAT identity

The IPAT identity makes a conceptual link between population, development, and technology, and different trajectories depend on the interactions between these determining factors. The IPAT identity has the following form:

$$I = P \cdot A \cdot T = P \cdot (Y/P) \cdot (I/Y) = I, \text{ where (Eq. 1a)}$$

- ❖ I = impact, i.e. use of natural resources or energy
- ❖ P = population
- ❖ A = affluence, an alternative term for per capita income,  $P/Y$
- ❖ Y = national output or GDP
- ❖ T = technology, or the efficiency with which production takes place, generally interpreted as the amount of resource use (or resource impact) per dollar of output.

Eq. 1a suggests a simple multiplicative relationship between the three constituent factors, P, A and T. Indeed, population is viewed in some of the scientific and policy literature as simply a proportional factor or multiplier of the environmental impacts of the more 'substantive' factors of economic growth, technological change and regulatory restriction. Other things being fixed, a doubling of population will lead to double the consumption of natural resources and energy. We know that this does not happen, however – other things are not fixed – overall moderating population growth will improve economic growth in emerging and low-income economies thus limiting the positive effects that population moderation will have on aggregate emissions. On the other hand moderating economic growth can limit growth in lower-income economies, affecting also the rate of population moderation. So once again, what might be a gain on one side can be lost on the other. Further, growth is required to meet the other substantive SDGs. Thus a radical decoupling of emissions from both population and economic growth has to be achieved.

The Kaya Identity has often been used to analyse the various drivers of climate change.

$$C = P \cdot A \cdot e \quad c = P \cdot (Y/P) \cdot (E/Y) \cdot (C/E) \quad (\text{Eq. 1b})$$

Where:

C = carbon emissions

P = population,

A = affluence =  $Y/P$ , where Y = Income (or consumption)

e = energy intensity (or energy consumption per dollar of output) =  $E/Y$ , where E is total energy consumption

c = carbon intensity (i.e. carbon emissions per unit of energy consumed) =  $C/E$

What this suggests is that the reduction of emissions will occur only if one or more variables in Eq. 1b are reduced. Two inferences can be drawn from this relationship. First, while a marginal and gradual reduction in emissions can be achieved through marginal changes in one or more of the constituent factors (P, A, e, and c), radical reductions implied by the Paris Agreement (including, e.g., reducing emissions to zero by 2050) can be achieved only through some combination of rapid decarbonization of energy use (i.e. reducing  $C/E$ ), reduction of the overall energy intensity ( $E/Y$ ) of the economy, reduction of the consumption level ( $Y/P$ ) of the world's rich and better off (both in the developed and the developing world), and reduction of the ultimate level of the population (P). All of these options present challenges.

# Chapter 3

## The Current State of our Data and Knowledge

**Coordinating Lead Authors:** Florence Daguitan (Tebtebba, Indigenous Peoples' International Centre for Policy Research and Education), Pali Lehohla (Pan African Institute for Evidence - PIE), Charles Mwangi (GLOBE Programme), Joni Seager (Bentley University), William Sonntag (Group on Earth Observation Secretariat), Graeme Clark (University of New South Wales)

**Lead Authors:** James M. Donovan (ADEC Innovations), Sheryl Joy Anne S. Gutierrez (ADEC Innovations), Michelle G. Tan (ADEC Innovations)

**Contributing Authors:** Amit R. Patel (Planned Systems International, Inc.)

## Executive summary

**There is a growing demand for environmental indicators and analysis, particularly analysis that addresses interlinkages across different environmental domains and between the environment, society and the economy** (*well established*).

There have been advancements in terms of collecting official statistics related to the environment, including geospatial statistics, particularly in terms of promoting environmental economic accounting and building geospatial information systems, which contribute to environmental monitoring. However, there are still methodological gaps in measuring some aspects of the environment, there is very limited information which links people and the environment, and there are capacity gaps in countries attempting to build their environmental information systems. {3.2}

**Measuring the nexus between gender and the environment has been identified as a high priority, as women and men, in many contexts, have differing rights over and access to the environment** (*well established*). Women and men have different vulnerabilities to environmental degradation and hazards,

and often play different roles in environmental management decision-making. Currently, only limited time series data and statistics are available on the gender-environment nexus. {3.5}

**Much environmental data collection is part of one-off studies or projects, limiting their usefulness** (*well established*).

Through the Sustainable Development Goals (SDGs) there has been a global recognition that monitoring the environmental dimension of development will require regular, standardized data collection, which can translate into time series statistics and indicators, including time series for geospatial data products. This will increase the emphasis on compiling high-quality information based on international best practices. {3.7}

**Transforming the provisioning of environmental data and statistics will require new and innovative means of data collection,** (*well established*) including new partnerships with the private sector, multilateral institutions, space agencies, non-governmental organizations and other partners. {3.8}

### 3.1 Introduction

This section provides an introduction to environmental statistics and data and covers the state of existing data and knowledge that contribute to any environmental assessment, including national-, regional- and global-level assessments. It attempts to elaborate the state of data collection and the use of data to compile statistics and produce indicators. Emerging areas of statistics, such as big data, citizen science and traditional knowledge – which are currently underutilized, but present tremendous opportunities for better measuring – are discussed in Chapter 25 of this report.

### 3.2 The demand for environmental statistics and data

Knowledge and data are essential bedrocks of environmental assessment. Without an evidence base to work from, conducting and publishing an accurate assessment is impossible. But what is an evidence base, and how do we generate it?

‘The Environment’ was traditionally considered to refer only to biophysical earth systems. But this paradigm is shifting. It is important not only to measure the state of the environment, but also to determine how environmental problems, which manifest in the biophysical environment, arise from social systems and economic arrangements, and how economic development and social well-being depend on the environment.

The GEO-5 report chapter on the *Review of Data Needs* presents the deficiencies in scientifically credible data on the environment; in particular, the report notes the need for time series on freshwater quantity and quality, groundwater depletion, ecosystem services, loss of natural habitat, land degradation, chemicals and waste, and other issues (United Nations Environment Programme [UNEP] 2012). It also acknowledges that the factual and scientific quality of an assessment rely on the quality and availability of data on the environment (UNEP 2012). Further, it indicates that more systematic data-collection can help governments, as well as regional and international bodies, to assess their progress towards international goals.

In his 2015 Millennium Development Goals (MDG) Report, Ban Ki Moon (**Box 3.1**) (United Nations 2015a) called for urgent and rapid improvements in data for the post-2015 agenda, especially its availability, reliability and timeliness. He urged governments to make substantial investments in their national statistics offices and systems, as well as to scale up the capacity and capability for producing high-quality data.

The Drivers, Pressures, State, Impact, Response (DPSIR) conceptual framework (see Section 1.6) is a useful framework for environmental monitoring and assessment. Many of the

drivers and pressures of environmental change are located in the social realm, and so are many of the impacts. Many environmental challenges are the result of inequalities in access to resources and institutions of power, as well as along the axes of gender, age, race, ethnicity, income and other social status.

As highlighted in the GEO-5 report (UNEP 2012), there is a need not only for regular monitoring data, but also for harmonization of data-collection approaches and methodologies. Governments rely on national statistical systems to provide the necessary data for national policy; however, historically, many national statistical systems have not considered environmental statistics to be within their purview.

### 3.3 History of environmental statistics

Historically, official statistics have risen in response to a clear demand from governments for information. The first Roman census was justified by the need for accountability in terms of taxation and military service (Hin 2007). National accounts were born out of the stock market crash of 1929 and the need for wartime statistics, which would allow countries to avoid economic catastrophe and provide information on how to pay for World War II (Stone 1947; Vanoli 2005). In 1947, the United Nations established the United Nations Statistical Commission (UNSC) to develop and promote statistical guidelines which could be used by countries for national monitoring. The scope of the Commission's work covers statistical methodologies for keeping stock of the economy, and for policy on global macroeconomic stability, including economic growth, price movements and population dynamics, migration, mortality, births and longevity – but not the environment.

The Brundtland Commission of 1983 led to the Framework for the Development of Environment Statistics which was first adopted by the UN Statistical Commission in 1984. Later, the UNSC worked on environmental economic accounting which arose from the 1992 Earth Summit. There have been three revisions of the System of Environmental Economic Accounts (SEEA) these include the SEEA 1993, the SEEA 2003 and the SEEA 2012 – the latest was adopted as a statistical standard in 2012 (United Nations 1993; United Nations *et al.* 2003; United Nations 2012). Additionally, the Experimental Ecosystem Accounts were adopted in 2013. The link between these two statistical frameworks forms the basis for monitoring progress towards sustainable development and focuses on the effects of life on the environment and that of the environment on life.

There was a 91 per cent participation by countries and territories in the 2010 census round, and a 95 per cent submission rate of national accounts to the United Nations Statistics Division (United Nations 2015b; United Nations 2017a). However, for the first six decades of the UNSC, progress in official statistics was mostly related to demography and economic statistics. The adoption of the MDGs, which included goals focused mostly on social development, and the desire to track progress as measured by the MDG indicators was transformational in terms of increasing investment in statistics. The MDG implementation efforts resulted in increased statistical capacity of countries to produce and use statistics on poverty, education, health, gender, environment and governance (World Bank 2002; Organisation for Economic Co-operation and Development [OECD] 2015; United Nations 2016a).

#### Box 3.1: Statement from Ban Ki Moon, 2015

“Strong political commitment and significantly increased resources will be needed to meet the data demand for the new development agenda.”

Ban Ki Moon, 2015 (United Nations 2015)

Environmental statistics and statistics disaggregated by location, gender, age, poverty and other factors were not a focus of MDG monitoring and therefore received less investment. These areas are a focus of the SDGs; however, many challenges remain in terms of measuring different aspects of the environment and also in creating disaggregated statistics.

### 3.4 Better data for a healthy planet with healthy people

Improved environmental data and statistics are required for many levels of decision-making, for environmental assessments at the local, national, regional and international levels, and for analysis of the interaction between the environment and the economy and society. A robust environmental statistics system, which is geospatially disaggregated, would ideally provide information that could be used for different purposes and at different levels.

#### 3.4.1 Measuring the environmental dimension of sustainable development

The context within which this report is produced is one where the MDGs have run their course. In September 2015, the United Nations General Assembly endorsed *Transforming Our World: The 2030 Agenda for Sustainable Development*, a global development agenda which captures goals and targets needed to achieve economic, social, and environmental development (A/RES/70/1). The Sustainable Development Goals (SDGs) represent a move away from treating social development in

isolation towards an approach aimed at sustainable prosperity, dignity for people, and a healthy planet through national action and partnerships.

In the quest for achieving these ambitious goals, the SDGs are defined around 17 goals, 169 targets and 244 indicators (inclusive of duplication) (United Nations 2017b). *Transforming Our World...* clearly notes that data requirements for the global indicators present a tremendous challenge to all countries. One study estimated that an investment of US\$ 1 billion per annum will be needed in order for lower-income countries to monitor the SDGs (Sustainable Development Solutions Network 2017). Thus, as highlighted in the 2016 SDG report, tracking progress on the SDGs will require a shift in how data are collected, processed, analysed and disseminated, including using data from new and innovative data sources (United Nations 2016b).

Although the SDG framework creates monitoring challenges, it also creates opportunities. It represents the first time that there has been an attempt to holistically include environment-related indicators in a global monitoring framework. Although the SDG framework has set out indicators for measuring across all 17 SDG goals, many of the indicators lack a statistical methodology. This is recognized in the framework by assigning each indicator to one of three tiers (see Figure 3.2). The inclusion of a broad range of environment-related SDG indicators can be used to leverage increased investment in environmental statistics and to promote their use.

Figure 3.1: SDGs data and knowledge framework

Figure 3.2: SDG indicator status

#### Tier 1 Indicator

Indicator has an internationally established methodology and data are regularly produced by 50 per cent of countries.

#### Tier 2 Indicator

Indicator is conceptually clear, but data are not regularly produced by countries.

#### Tier 3 Indicator

No internationally established methodology or data collection.

Source: United Nations (2018, p.3)

**Figure 3.3: Environment-related SDG indicators by goal and tier**

Source: United Nations (2018).

There are 93 SDG indicators directly related to the environment (**Figure 3.3**). There are also a number of additional indicators that are indirectly related to the environment (e.g. poverty, zoonotic disease, nutrition and life expectancy, economic growth, inclusive societies and policy processes which are not included in **Figure 3.3**). The environment-related SDG indicators are spread across all of the SDGs, with at least one environmentally relevant SDG indicator for each, except Goal 10 – which reflects the cross-cutting nature of the SDGs and the interactions between people, the environment and the economy. However, of the 93 environment-related SDG indicators, only 34 currently have an existing agreed methodology and data that are available from most countries (Tier I). The other indicators have either been given a Tier II or III status (27 and 34 indicators, respectively) by the Inter-Agency and Expert Group on the SDG indicators (**Figure 3.4**).

Monitoring the environmental dimension of the SDGs will not only require research and development in terms of statistical methodologies but will also require investing in environmental statistics and utilizing new data sources to achieve a data revolution. Traditional data collection by national statistical offices cannot be the only source of data, but countries will need integrated data systems which bring together official statistics, earth observation, citizen science, big data and traditional knowledge. Integrated data systems can bring many sources of information together to provide a more complete picture. Environmental data integration includes:

- ❖ bringing together ethnographic information about environmental changes as experienced on the ground;
- ❖ a participatory understanding of personal experience; indigenous and traditional knowledge; geospatial information about people and the environment;
- ❖ combined information on the environment and women, the poor, and other vulnerable groups in order to reveal patterns and challenges hidden in other systems of knowledge;
- ❖ knowledge from Big Data on sustainable consumption and production patterns; and

- ❖ poverty dynamics within and between countries, some dimensions of which can be revealed by satellite observations of 'the earth at night' or deforestation boundaries.

**Figure 3.4: GEO-6 major data gaps organized by respective chapter**

#### DRIVERS

Land use and ownership  
Stockpiling and pesticides

#### OCEANS

Polar region forecasting  
Environmental disasters  
Planetary boundaries  
Survey systems

A new approach to data and knowledge systems with increased emphasis on an evidence-based approach to decision-making is crucial to meet the various SDGs. By placing these systems at the forefront for all end users, cross collaboration can be innately encouraged to foster new skills, technologies, and sources of data. In turn, our knowledge of sustainable development will improve, alongside our understanding of the SDGs. However, organizational and methodological challenges will arise regarding data privacy, ownership and use (Sustainable Development Solutions Network 2017).

### 3.4.2 Thematic data gaps

In almost all thematic areas (including biodiversity, land, air, water and oceans), available data are lacking (Figure 3.4), particularly in developing countries. Environmental indicators linked to industrial activities are easier to measure and monitor, for example energy consumption or water use. Land cover and ecosystem extent can be assessed on a broad scale using satellite remote sensing, but not always with the necessary resolution. The effects of environmental change, air and water pollution, and other environmental conditions are particularly difficult to measure (UNEP 2012); hence the need to explore a paradigm shift on environmental monitoring approaches – depicting the social orientation and complementing the approach with physical attributions.

The following is a brief description of some of the major data gaps from the thematic chapters in Part A of this report.

#### Drivers (Chapter 2)

National-level population data are relatively sound for most countries due to government census requirements, but weaknesses arise from aggregation across sectors of the population. National census data are generally insufficient to answer important intra-household questions, such as contraception use and access, fertility, household decision making and family structure (e.g. age of marriage). To be properly understood, these and other variables should be disaggregated by age, gender, race and other socioeconomic factors. Urbanization data are plagued by similar issues of national aggregation. There is a lack of information on small and medium-sized cities, and inconsistency in the scale of reporting. For both population and urbanization, there need to be standard agreements on statistics at a global scale, and greater consistency and coverage. Other significant data gaps include rural to urban migration, the role of nuclear households, the distribution of benefits provided by technology, and patterns of production and consumption. Uncertainty also exists in the myriad factors affecting economic development, and dependencies between this and other drivers. For example, financial estimates of the cost of unsustainable practices and impacts of climate change require greater accuracy and transparency, given that, while numbers exist, there is low confidence in their accuracy.

In addition to gaps in raw data, gaps exist in the mechanistic understanding of the driver processes. Future technologies and events will alter the global landscape and qualitatively change the roles of other drivers. For example, automation may change the nature of transportation, which would have flow-on effects to many other areas. The impact of climate change on human health requires better analyses and understanding of current

and future links between these factors. More data are needed on the effect of climate change on human demographics, including migration estimates at finer scales (McMichael, Barnett and McMichael 2012). There is sectoral imbalance in knowledge on the effects of climate change, with impacts on the energy sector being well understood, while impacts on land use, ecosystem processes and functions, and intersectoral issues are not.

#### Air (Chapter 5)

An overarching issue with air quality data is that, unlike meteorological variables, few air pollutant concentrations are measured with sufficient spatial and temporal coverage. Therefore, the effects of most chemicals are estimated by using other (measured) chemicals as proxies, which is likely to be inaccurate in many cases. For example, only a few persistent, bioaccumulative and toxic substances are measured, and their data are globally patchy. Where monitoring does exist, it is biased towards developed countries, compromising analyses of air pollution versus human health in developing countries. There is a general need for capacity-building to facilitate the measurement of air pollution in developing countries, both for national benefit and to complete global coverage. Bias in air quality sampling also exists within countries, and there is a need for more sampling in areas of low socioeconomic status (e.g. informal or slum dwellings).

Impacts of air quality on human health gained attention in the Global Burden of Disease Study – a global study of factors influencing human health (World Health Organization [WHO] 2018), which elevated air pollution to a top priority. Instead of relying only on cities that have air quality monitoring, satellite data and modelling were used to estimate air pollution at large scales (Brauer *et al.* 2016). Additionally, there are currently few consistent global emissions inventories. Inventories are gathered or modelled in some regions, but data quality and sources vary. There are, however, consistent inventories available at a European level and at international level for a selection of pollutants (e.g. under the United Nations Economic Commission for Europe Convention on Long-range Transboundary Air Pollution).

Efforts should focus on greater sampling coverage and/or modelling, potentially with sensors or satellites. The Copernicus programme aims to measure a number of air quality variables on a regular basis and provide data for all countries. Another European initiative for data reporting is the Air Quality Directive, which provides for statistical data that are produced annually, and an online map of air quality that is updated every 6 hours.

#### Biodiversity (Chapter 6)

Biological data and knowledge are sparse compared with the complexity and diversity of biological systems. In general, data paucity increases at finer spatial scales, and at higher taxonomic resolutions. Estimates of the total number of species vary between 2 million and 13 million (Costello, Wilson and Houlding 2012; Scheffers *et al.* 2012), with the majority (86 per cent of terrestrial species, and 91 per cent of oceanic species) believed to be undescribed (Mora *et al.* 2011). Invertebrates and deep-sea ecosystems are particularly poorly described. Biologists increasingly use genetic information to identify species (a technique known as DNA barcoding) (Hosein *et al.* 2017), but more traditional taxonomy is still needed to describe morphological traits.

Gaps in data of ecological processes and ecosystem and community structure are even greater than gaps in species information. Examples include ecosystem function and services, which are understood conceptually but are often difficult to measure. A consequence of this is an inability to effectively prevent species invasions, which is considered by some to be the second greatest threat to global biodiversity (Doherty *et al.* 2016).

There is substantial uncertainty in the extent of climate change impacts on biodiversity, and bioinformatic challenges in processing the volume of earth observation data relevant to climate-driven biological change (e.g. in forest cover). Current solutions to such big data problems include change-detection software, which minimizes the need to store data for every fly-over, and multidimensional data structures such as 'data cubes', which manipulate large amounts of raster data efficiently.

Global initiatives to advance biological data include the Convention on Biological Diversity's Global Taxonomy Initiative (Siebenhüner 2006) and the Global Biodiversity Information Facility (GBIF) (Yesson *et al.* 2007). GBIF species occurrence records now cover all parts of the globe (1 billion records referring to 1.7 million species); (GBIF 2018), and its taxonomy follows the Catalogue of Life (<http://www.catalogueoflife.org>) using established Biodiversity Information Standards (TDWG) for data transfer (<http://www.tdwg.org/>).

Much indigenous ecological knowledge (e.g. medicinal plants) is translated by word of mouth and risks being lost if undocumented (McCarter *et al.* 2014). However, a framework has recently been developed for connecting indigenous knowledge with other knowledge systems (Tengö *et al.* 2013), such as international assessments (Sutherland *et al.* 2014), and some indigenous knowledge is now captured digitally (Liebenberg *et al.* 1999; Stevens *et al.* 2014).

In addition to data gaps, there are deficiencies in data sharing and access. Some biological problems are inherently regional or global and require coordinated multinational management. A field where this is a major problem is transnational environmental crime (White *ed.* 2017), which includes harvesting, transporting and tracing trade of endangered species, illegal mining, fishing and deforestation. Improvements in shared data infrastructure are essential for effective regulation in this area.

### **Oceans (Chapter 7)**

Ocean data have many gaps, which is unsurprising since satellite observations cannot penetrate below surface waters. Most oceanic data are collected by direct measurement or modelling, so it is difficult to obtain good coverage for a vast environment that extends over 70 per cent of the earth's surface. Some issues exist through lack of global coordination, as both coral reefs and marine litter lack global databases. The National Oceanic and Atmospheric Administration (NOAA) maintains the largest coral reef database, but it does not draw upon all sources globally. Similarly, marine litter data are collected by different countries with different protocols and have not been globally consolidated. In addition to litter abundance and distribution, significant knowledge gaps exist regarding the ecological impacts of marine litter, including the

toxicity of ingestion, impacts of nanoparticles, microplastics, and how plastics ingested by fish impact human consumption.

Global fish catch data are maintained by the Food and Agriculture Organization of the United Nations (FAO), to which all countries report national catch and yield. Commercial fishing catches are well monitored in developed countries, but are almost certainly underestimated since illegal fishing constitutes as much as 40 per cent of all catch in some areas (Agnew *et al.* 2009). In countries with fewer resources to devote to reporting, fishing estimates are often based on a small number of samples and are therefore less reliable. Research vessel costs are a major impediment to obtaining fisheries-independent data, particularly in developing countries where even catch monitoring in ports may not be economically viable.

### **Land (Chapter 8)**

Land is one of the most data-rich domains due to the effectiveness of earth observation in monitoring land surfaces, but there are still notable data gaps and quality issues. Earth observation generally measures the quantity rather than the quality of change, and is unable to measure certain processes. For example, there is agreement that land degradation has increased, but it is not done often and is inconsistently measured. The interrelationships between the Normalized Difference Vegetation Index (NDVI) and land degradation are often difficult to generalize and transfer, since land use and biophysical conditions are changing regionally. While forest cover data have improved since the mid-1990s and some broad-scale data are maintained by FAO, other data exist in multiple databases that are not always comparable. Soil erosion, salinization, desertification and change in ecosystem services are all difficult to measure from satellite images, and there are questions as to the appropriate scale of observation. There is no global database or standardized measurements of soil erosion, preventing a globally coherent or comprehensive assessment. Other difficult areas are land tenure and cadastral (map-based) information, since there is no global standard for defining land use, and systems are not comparable across countries.

### **Freshwater (Chapter 9)**

Data on fresh water suffer from spatial and temporal patchiness, and a divide between variables that can be remotely sensed by earth observation versus those that cannot (Lawford *et al.* 2013). Data-deficient areas at all scales include water quality, water consumption, groundwater quantity, water withdrawals and wastewater. The SDGs require monitoring of ambient water quality, but not all countries have the capacity or will to meet these reporting requirements. There are better data for surface-water quality than for groundwater, but these are still patchy. Earth observation systems measure optical qualities of water (chlorophyll, salinity, turbidity), but cannot measure nitrogen or phosphorous concentrations. In recent years, progress has been made in using satellite data from the GRACE mission to estimate changes in groundwater storage (depletion), but assessing groundwater resources requires the collection of direct data which are relatively expensive as they require access to groundwater through wells or boreholes. There are also gaps in glacier, snow and ice data, and uncertainty around impacts of climate change (Salzmann *et al.* 2014), though the Copernicus programme may address this on a global scale with a satellite dedicated to monitoring snow/ice cover. Some other variables are difficult to measure by any

means, such as groundwater and saltwater intrusion, which are mostly understood by modelling rather than observation. These models are in urgent need of reliable on-the-ground data for calibration and verification. Geopolitical issues of water use, such as transboundary water sharing, are another area requiring more data, particularly at times of water scarcity.

Citizen science may offer some solutions to issues of freshwater sampling coverage and basic monitoring of groundwater levels. Examples include the use of mobile applications to monitor water quality (Lemmens *et al.* 2017) and the use of testing kits in EarthWatch Freshwater Watch (<http://www.freshwaterwatch.thewaterhub.org/>) and other volunteer groups (Overdevest *et al.* 2004). An early form of citizen science has successfully been deployed for many decades in Netherlands where volunteers from across the country measure groundwater levels in piezometers bimonthly, contributing to the building up of long-term time series of groundwater data in the country. However, citizen science initiatives usually involve simple water monitoring and do not measure the suite of modern pollutants such as antibiotics, persistent organic pollutants, current use pesticides, microplastics, nanoparticles and endocrine disruptors.

### 3.5 Gender and social-environment intersectionality

The paradigm shift that is bringing social analysis into the heart of environmental assessment has developed since the mid-1990s with the emergence of gender-disaggregated environmental analysis and analysis focused on other vulnerable groups. This section will focus on the gender-environment nexus; however, many of the issues presented could be applied to other vulnerable groups. Broader equity issues, including, importantly, North-South inequalities in environmental footprints and impacts – which are themselves gendered – are addressed elsewhere in this report.

The role of gender in environmental analysis will accelerate as the social equity and equality commitments of Agenda 2030 shape global policymaking (**Box 3.2**).

At the heart of gender analysis is the understanding that virtually all environmental relationships, including drivers and impacts, are 'gendered'. Socially constructed gender roles and norms position men and women differently in relation to the

environment. Men and women are often exposed to different environmental problems and risks; in turn, this may mean that men and women have different perspectives on the extent and seriousness of environmental problems, and on what solutions might best be attempted or deployed. Further, because of the social construction of gender roles, men and women are often positioned differently in terms of being able to take action or being taken seriously as agents of environmental interpretation and change.

Gender analysis requires new approaches to the structure of environmental inquiry. Analysing the environment through a gender lens requires new and different questions, brings to the foreground different dimensions of human-environment relationships, and requires different methodological tools and approaches. Gender analytical lenses encompass 'the environment' in both its physical and social aspects, and in the interactions of these. Gendered commitments to "lift the roof off the household" in data collection reveal intra-household dynamics of resource utilization and decision-making, which are often critically important in understanding local environmental behaviour and environmental outcomes (Seager 2014).

Gender analysis also brings to the fore intersectionality – an understanding that social relationships with the environment are seldom shaped by a single social identity, but rather by a combination of gender identities and norms, as well as other social identities such as race, sexuality and class.

The UNEP *Guidelines for Conducting Integrated Environmental Assessment* (UNEP 2017) reflect these new approaches by bringing to the fore gender-informed questions that should be integrated into environmental assessment from the earliest planning stages (**Box 3.3**).

Data availability and statistical systems have not kept pace with the interest in and demand for gender-disaggregated analysis in environmental assessment. The GEO-5 assessment notes the lack of – and need for – gender-disaggregated environmental data (UNEP 2012). One of the most consistent messages in the field of gender-disaggregated environment analysis is that this information is crucial to a comprehensive analysis (United Nations 2015a; UNEP 2016). Some progress has been made since the GEO-5 assessment, and UNEP (2016) synthesizes the data and analytical approaches that are now

#### Box 3.2: Gender statistics

"Gender statistics are defined as statistics that adequately reflect differences and inequalities in the situation of women and men in all areas of life...First, gender statistics have to reflect gender issues, that is, questions, problems and concerns related to all aspects of women's and men's lives, including their specific needs, opportunities and contributions to society. In every society, there are differences between what is expected, allowed and valued in a woman and what is expected, allowed and valued in a man. These differences have a specific impact on women's and men's lives throughout all life stages and determine, for example, differences in health, education, work, family life or general well-being. Producing gender statistics entails disaggregating data by sex and other characteristics to reveal those differences or inequalities and collecting data on specific issues that affect one sex more than the other or relate to gender relations between women and men. Second, gender statistics should adequately reflect differences and inequalities in the situation of women and men. In other words, concepts and definitions used in data collection must be developed in such a way as to ensure that the diversity of various groups of women and men and their specific activities and challenges are captured. In addition, data collection methods that induce gender bias in data collection, such as underreporting of women's economic activity, underreporting of violence against women and undercounting of girls, their births and their deaths should be avoided..."

Source: UNSD (2015)

available. Nonetheless, very little information is available about the different needs of men and women, their different use of resources, and their different responsibilities in contributing to conservation and sustainable development.

Even less information is available to support intersectional analysis of gender with age, race, caste or class dynamics. Existing data on gender and the environment are fragmented and scattered among small and often grey-literature sources

or across hard-to-access scholarly reports. There are almost no common standards or complementarities across countries, making it almost impossible to aggregate and compare issues across regions. The lack of sufficient long-term data further impedes gender-disaggregated environmental assessment because relationships between gender and the environment may only become evident over long time periods.

The absence of gender data undercuts the momentum towards further gender-environmental analysis – ‘what’s not counted is assumed to not count’. In the absence of data, environmental assessments remain partial; establishing baselines, monitoring progress and assessing outcomes are almost impossible. Progress towards SDG commitments to gender equity and equality in all domains, including the environment, will be impossible to measure without substantial improvement in gendered data.

Even simple gender-disaggregated data-based analysis, such as that on average time spent in unpaid work by men and women (**Figure 3.5**), can reveal important gender dynamics. The burden of unpaid work restricts women, more than men, from undertaking paid work and from participating fully in civil and economic spheres. Figure 3.5 illustrates the uneven burden of unpaid work between men and women. Many hours of women’s unpaid work, especially in poorer countries, are spent in directly managing local environmental resources to meet the needs of household water, fuel and food. At the same time, ‘time poverty’, which is produced by the burden of unpaid work, means that women are less likely than men to be available for environmentally relevant training, nor are they available to participate in formal processes relating to environmental use, management and decision-making.

### Box 3.3: Gender-informed questions

- ❖ What are the geographic locations and subject areas, sectors and activities in which gender difference and social class impact one’s relationship with the environment?
- ❖ Are there any other intersectional issues that might need to be considered (e.g. how different cultural/ethnic/class groups use, imagine and/or relate to place and are there any conflicts between these groups)?
- ❖ How do general differences between socioeconomic classes, in relation to the environment (as mapped in reports such as the *Global Gender and Environment Outlook*, UNEP 2016) apply to the environmental issues undergoing assessment?
- ❖ What are the differences in behaviour of men, women, boys and girls in relation to the environmental issues undergoing assessment (as mapped in reports such as the *Global Gender and Environment Outlook*?)
- ❖ Are gender-disaggregated data available to understand that relationship or will it need to be collected?

MENA, Middle East and North Africa; SA, South Asia; ECA, Eastern and Central Africa; LAC, Latin America and the Caribbean; EAP, East Asia and the Pacific; SSA, sub-Saharan Africa; NA, North Africa.

Source: Ferrant, Pesando and Nowacka (2014, p. 2).

The expectation that environmental assessments will include gender analysis and data is achieving mainstream acceptance. In 2016, UNEP produced the *Global Gender and Environmental Outlook* (GGEO) entirely through a gender lens. The GGEO report concluded that the effectiveness of environmental decision-making would be enhanced by “Strengthening the focus on developing, collecting and analysing gender-disaggregated data, indicators and other information, including at the intra-household level.” (UNEP 2016, p. 201).

The SDG target 17.18 specifically calls for improved collection and availability of gender-disaggregated data: “By 2020, enhance capacity-building support to developing countries, including for least developed countries and small island developing States, to increase significantly the availability of high-quality, timely and reliable data disaggregated by income, gender, age, race, ethnicity, migratory status, disability, geographic location and other characteristics relevant in national contexts” (A/RES/70/1).

The GGEO provides a summary of the most complete gender-disaggregated data sets available as of 2016. These include several gender-disaggregated agricultural indices (from FAO) on indicators such as agricultural employment and landholders; cross-national comparative information on access to and ownership of land (from FAO, the Organization for Economic Co-operation and Development [OECD] and the World Bank); and sex-disaggregated burden-of-disease data for a few environmental factors (Prüss-Ustün *et al.* 2017).

Additional large-scale efforts are under way to collect and analyse environment-related gender-disaggregated data:

- ❖ in 2014, the United Nations Educational, Scientific and Cultural Organization (UNESCO) launched a project to identify gender and water priority indicators (UNESCO 2014);
- ❖ the FAO Gender and Land Rights Database “was launched in 2010 to highlight the major political, legal and cultural factors that influence the realisation of women’s land rights” (FAO 2018). By 2018, the FAO database had data from more than 80 countries, and the FAO ‘Legal Assessment Tool’ maps the intricacies of men’s and women’s access to land.

The prospects for improving gender-disaggregated environmental data are promising and the expectations for data collection for the SDGs should accelerate efforts to systematically collect both sex-disaggregated (indicators specifically related to biologically rooted activities, roles and impacts), as well as gender-disaggregated (related to social roles and impacts) environmental data. There remains, however, a considerable gap between demand and supply.

### 3.6 Equity and human-environment interactions

Assessing human-environment interactions requires data, knowledge and integrated approaches as outlined in Chapter 1 of this report. A balanced evaluation of existing data and scientific results can lead to balanced policy choices. However, is the knowledge base able to provide a balanced story about human-environment interactions? This leads to three key questions, as shown in **Figure 3.6**.

**Figure 3.6: Equity questions in data and knowledge**

**Who pays for data and knowledge and for what sorts of data and knowledge?** All data and research are funded by specific actors – the state, but also non-state actors such as civil society, industry and philanthropists. There is clear evidence that states invest large sums of money in natural science and technology research, but there is significantly less invested in environment- and resource-related social science and equity-related research. For example, a study of funding in the United States of America shows that between 1970 and 2015 social sciences received very little funding in comparison with other fields of study (National Science Foundation 2017).

**Whose interests do the existing data and knowledge serve?** Research questions and data tend to serve dominant interests, for example those identified by the funding agencies. They may also serve disciplinary interests rather than human-environment interactions more integratively (McMichael, Butler and Folke 2003). Furthermore, although there is need for data and knowledge on the causes and impacts of internally displaced people, such data are not yet available (Bennett *et al.* 2017, p. 11). The need for disaggregated data is vital to address issues of equity, but such data and knowledge are limited.

**Whose data and knowledge counts and why?** In international assessments there is increasing evidence that researchers come from the richer ‘developed’ world, rather than the non-English speaking and/or developing world. For example, 87 per cent of the world’s researchers, 92 per cent of the research budget and 94 per cent of scientific publications come from the G20 countries (UNESCO 2015). In 2015, the majority of authors in the Intergovernmental Panel on Climate Change (IPCC) came from developed countries with significantly fewer from developing countries (Schulte-Uebbing *et al.* 2015).

There is little assessment in any of the environmental literature of the politics of data and knowledge, and this is challenging.

### 3.6.1 Environment and economy

A number of SDGs depend for their realization on understanding and properly taking into account the costs and benefits of environment-economy relationships. Most importantly, the SDGs and natural capital accounting indicators provide insight into the value of 'nature's contributions to people', human societies more broadly, and of the cost of residuals such as pollution and waste. The economics of nature or natural capital accounting involve the assessment, measurement, aggregation and valuation of these contributions, to help policymakers ensure that this value is reflected in the economic activities of production, consumption, trade and investment through such instruments as pricing, costing and regulation. Evaluating the economic dimension of the environmental impacts of economic activities helps policymakers realize synergies between economic and environmental issues, gain efficiency in the allocation of limited resources and avoid trade-offs (or minimize them where they are inevitable). Any such evaluation should take into account that economic activities are increasingly characterized by global chains (e.g. investment, trade), and the role of such 'teleconnections' is crucial in determining overall impacts. Therefore, what we do to sustain environmental resources in one place may be at the expense of resources or environmental quality elsewhere. The System of Environmental Economic Accounts provides a framework for analysing the interactions between the environment and the economy. It includes information on four policy quadrants, namely: access to services and resources; managing environmental resources supply and demand; the state of the environment; and risks and extreme events (United Nations 2014).

When considering the benefits of nature, a fundamental issue is whether these values are comparable with and substitutable by other economic benefits. Most conventional economic analysis assumes substitutability of factors of production, called 'weak sustainability', when applied to natural capital (Solow 1974; Hartwick 1977). But there are many instances when the contributions of nature to human life (e.g. the regulation of the climate) cannot be provided by other human activities. These situations of 'strong sustainability', often related to the planetary boundaries, need to be revealed through robust analysis. Such analysis will need to rely on methodological diversity, using insights from ecology, economics, social and cultural studies, and recognizing their dynamic evolution.

In natural capital accounting and in the System of Environmental Economic Accounting, methodologies may be used to give monetary value to environmental benefits and costs, so that they may be compared with other economic activities and costs. Alternatively, in some cases, only the stocks and flows of environmental resources and residuals are measured using an accounting framework as opposed to including a valuation. An accounting framework provides information on the use of environmental resources, such as water and energy, and the residual to the environment, such as emissions and wastes, by industrial classification.

For economic valuation, the valuation should always be applied in a way that it can capture trade-offs and the demand for resources for competing uses. It should also be recognized that there are numerous environmental situations in which,

due either to lack of data or absence of credible science or methodological agreement, economic analysis has limited scope.

Economic analysis of the environment can be oriented towards the wider goals of the United Nations system, and the SDGs related to peace, human rights, equity and security, as well as sustainability. It needs to recognize the complexity of environmental-economic interactions and highlight uncertainties, through clear and simple communication.

Sustainability, and the policies necessary to achieve it, should focus on trends in per capita wealth, as well as flows of income and non-monetary benefits. It is the natural capital stock that generates nature's contribution to people, and correct wealth accounting in relation to the environment and resources, avoids the mixing up of income and wealth.

Macro-models are required to assess national and global outcomes of policies for the use of resources and the environment. Recent results from use of these models suggest that the conventional perception of the economy and environment having a trade-off relationship may be incorrect. Increasingly, 'green economy' analyses seem to suggest that natural resources are an essential input to sustainable economic growth. From this perspective, an appropriate 'economics of nature' could be a great enabler of both conservation and development. Such messages need to be transmitted with clarity and confidence.

### 3.6.2 Environment and health

The environments in which we live are a key determinant of human health and well-being. The physical environment provides us with the air we breathe, the food and water required for sustenance, solar radiation that provides heat and light, and more. These are direct effects, but indirect effects are also important in supporting healthy ecosystems, which in turn provide food security and other ecosystem services. The social environment also has a strong influence on health and well-being, as clearly shown through socioeconomic gradients in health, whereby social disadvantage is associated with poor health and well-being across a wide range of diseases and health-risk behaviours (Friel and Marmot 2011). Degradation of our environment (e.g. air pollution, contamination of food and/or water, insufficient or excessive sun exposure, excessive noise, conflict and war) adversely affects food and water security, health and well-being.

Exploring the links between the environment, in its broadest sense, and human health and well-being requires measurement of the 'exposure' (the environmental factor of interest) and the 'outcome' (some measure of health and/or well-being). The next step is to assess whether there is a causal relationship between the exposure (e.g. air pollutants, conflict, green space, noise) and the outcome, which typically requires good study design, appropriate statistical methods, and causal analysis. The size of the effect, coupled with an understanding of the prevalence of the exposure in the population, can be used to provide an attributable effect (i.e. what proportion of the health outcome is caused by exposure to the environmental risk factor) (Prüss-Ustün *et al.* 2017). In addition to analysing exposure to certain contaminants, analysis of environmental

conditions and health and well-being can also reveal underlying relationships between health and the environment. For example, data on underweight children, malnutrition and other food security indicators can be analysed through an environmental lens to better understand the relationship between climate change and food security, health and well-being.

Environmental exposure can be directly measured at the individual level (usually only for relatively small numbers of people) or inferred at the individual level or at an ecological level using data from routine monitoring (e.g. of air and water quality, levels of solar radiation, or modelled, for example using combinations of atmospheric variables to estimate climate change-related exposures). These methods can also be combined, for example, where data from multiple weather stations are used to calculate individual exposures at different locations within an area (Miranda *et al.* 2016). Exposure measurement is more precise for some environmental factors (e.g. blood lead levels) than for others (e.g. lifetime exposure to noise pollution) (Klompmaaker *et al.* 2018), and for short-term rather than long-term (e.g. lifetime) exposures. Here, large sample sizes ('big data'), plus innovative study designs and data analysis, are required, but there must also be recognition of the potential biases within these 'noisy' data sets (Ehrenstein *et al.* 2017).

Data to assess the burden of the health outcome with environmental factors are available at the individual level through epidemiological studies, and from administrative databases (e.g. hospital separations data, where modern data linkage methods can allow examination of individual-level data). However, considerable challenges remain to using administrative data due to ethical issues around protection of individual privacy. Administrative data can also be used in ecological studies (e.g. of the effect of air pollution on hospital admissions). For some health outcomes in some countries, surveillance through disease registries provides comprehensive and accurate incidence and mortality data. These can be linked to other data sets to derive associations at an individual level (Korda *et al.* 2017), or used in ecological studies to assess relationships between disease and environmental parameters (Adams *et al.* 2016). The Global Burden of Disease (GBD) Study is a valuable data set for disease-specific incidence and mortality (GBD 2016 Causes of Death Collaborators 2017; GBD 2016 Disease and Injury Incidence and Prevalence Collaborators 2017). The GBD is now updated annually and seeks to collect the best possible health (typically disease) data from all countries to provide comprehensive estimates at the global, country and, for some countries, regional levels. In addition, the GBD Study estimates health loss through morbidity, as well as disability adjusted life years (DALYs) and health adjusted life expectancy (HALEs) (GBD 2016 DALYs and HALE Collaborators 2017). However, additional disaggregated information on who is impacted and on location, which would be necessary for a comprehensive assessment, is typically not available. Recent developments in 'omics' technologies – genomics, metabolomics, exposomics, epigenomics and others – deliver a huge amount of data that may allow assessment of the effects of environmental exposures on human health and well-being. However, challenges remain in separating out effects of specific exposure (e.g. the various

components of 'air pollution') and accurately quantifying effects attributable to exposures:

- a) that are difficult to measure precisely,
- b) have non-linear dose-response or threshold effects,
- c) when exposure levels change over life, or
- d) have both risks and benefits to human health.

### 3.7 Existing data systems

Official statistics, national geospatial data, and Earth observation monitoring data often are not part of a single data system at the national level, and there is a need for better integration of data from these sources in assessments. Although gaps remain in official statistics, national geospatial data and Earth observation data, these data sources are currently being used for environmental assessment and are better developed globally than the emerging tools for environmental assessment presented in Chapter 1.

#### 3.7.1 Official statistics

The disciplines of official statistics and Earth observation have developed independently and manifestations of their interconnectedness have been sporadic. The relationship has benefited from guidance emanating from the national statistical systems through the following developments: adoption of the System of Environmental Economic Accounting (SEEA) under the Central Framework in 2012, adoption of the SEEA Experimental Ecosystem Accounts in 2013 and the revised Framework for the Development of Environment Statistics in 2013. These three statistical frameworks provide an increased methodological basis for statistics; however, there is still a need to scale up statistical production and to involve more actors in the production of environment statistics, including local-level actors. Additionally, there remains a need for methodological guidance on the interactions between society and the environment, including the gender dimension.

Technological change – including better satellite data, monitoring stations and personal electronic devices – is changing the data landscape, including through citizen science. The data revolution and its technological derivatives, namely big data and citizen science, unleashed new possibilities for measurement, potentially disrupting existing organizational and institutional relationships in the management of measurement and production of scientific knowledge. The response to these new manifestations of technology-inspired measurement have been led by, among others, the United Nations Committee of Experts on Global Geospatial Information Management (UN-GGIM). However, it is likely to be long before the urgent need of integration is achieved. There remains a need to better utilize technologies, including mobile applications, smart devices and other tools, to make data accessible to populations and to provide an interface for making citizen science data discoverable.

#### **The imperative for statistics and data**

The injunction of 'leaving no one behind' imposes a high premium on the production and delivery of disaggregated data by all attributes possible, including (importantly) by local area. In so doing, the SDGs bring to bear the importance of

geospatial data and statistics. A geospatial statistical approach to measurement provides a transformative infrastructure that improves the information necessary to 'leave no one behind' through analysis of interactions and causality at the local level and for particular populations.

#### **The SDG indicator framework**

While the SDG agenda is bold and ambitious, it is not possible to cover everything at the same time. Therefore, the ability to prioritize and sequence is strategic for success in the delivery of measurement to the global agenda. So, which data, which statistics and which indicators?

An attempt to answer the questions cannot be made without historical experiences of global development measurement exercises, of which the MDGs represented the most enlightening. In his 2015 MDG report, the United Nations Secretary-General notes with regret that, first, statistical information is collected with a major temporal lag. Yet, today's world is a fast moving one requiring real-time data; second, that the information is highly aggregated and lacks locational specificity for use in directing interventions; and third, there is minimal resource allocation to countries and institutions that require data the most for development (for their people and environment).

That the nature of the problem has been defined does not imply that the questions the problem raises should not be answered. The benefit of defining the problem is in identifying with a greater level of clarity what needs to be done in prioritizing and sequencing.

With regard to indicators, official statisticians, under the guidance of the UNSC, have worked hard to identify an indicator framework and the feasibility of indicators that would feed into the framework. However, the design of the framework has, in practice, been directed towards the number of indicators, rather than to an architecture that would determine the indicators. The existence of the framework and the ability to identify indicators feeding into the framework is a commendable start.

In relation to the Global Environment Outlook, it is more important to note that the task becomes even more serious and politically challenging given that tens of the goals in the SDGs relate directly to or are closely linked to the environment. Perhaps this will lead to a different GEO outcome.

As defined in Section 3.1, less than a quarter of the environment-related SDG indicators are Tier I. This gives some idea of the difficulty of measurement, including resourcing of the statistics systems, in some countries.

The former United Nations Secretary General has recognized the need for clear coordination mechanisms for data and statistics. In this regard, the Secretary-General called on countries to recognize the significance of coordination among national agencies (**Box 3.4**), including national statistical institutions, in providing, encouraging and enforcing compliance with statistical standards through principles, legislation and practice notes.

#### **Box 3.4: Statement from the United Nations Secretary-General**

"National statistical offices should have a clear mandate to lead the coordination among national agencies involved and to become the data hub for monitoring."

Ban Ki Moon, United Nations Secretary-General 2007-2016,  
(United Nations 2015a)

#### **Measuring the environment in the context of the SDGs**

Accurately assessing the interaction between people and the environment will require new data sources and new tools for environmental assessment. For example, geospatial information can be incorporated with population maps to determine the regional environmental issues that affect people (e.g. where poor people live and where water quality issues are).

The key driver to the exponential growth of access to and use of technology has been the ability of technology to create and push towards common standards. Through this innovation, a movement has emerged towards standardized forms of data to be collected at a much lower cost. This has made collection of larger amounts of data a lot more attractive. More importantly, technology has unleashed possibilities for the use of geospatial statistics and a greater ability to observe changes in the environment.

Environmental data, statistics and knowledge are the foundations of successful environmental assessments. Remote technologies, Earth observation systems and national statistical offices remain the leading generators of environmental data. New and emerging knowledge frameworks and data capacities in database management, citizen science, disaggregated social and gender analysis, big data, data visualization tools, spatial modelling, social media and the Internet offer opportunities to collect and disseminate information. Collectively, data aggregated from these approaches improve capacity to support strategic decision-making processes that are based on wide-ranging and multidisciplinary knowledge. Effective monitoring of environmental trends is critical to clean up environmental damage.

The disaggregated and location-based information needed to 'leave no one behind' is believed to be achievable, and this meets the requirements for effective monitoring of environmental trends.

If we are, however, true to the notion of 'leaving no one behind' as prescribed in the SDGs, then multiple methods need to be handled by information management systems. These include the well-established traditions of statistical standards and the future of statistics is enhanced with the availability and analysis potential of land information systems. Furthermore, new technologies and their capabilities in the data and geographic space create new ways for citizens to participate in science and also to increase the possibilities of environmental data integration.

The challenge, however, for these new knowledge platforms to be useful, is if they are supported by an institution. First, can they be seen as systems of today and tomorrow that attract reasonable resources, and that enhance the well-being of people and the planet? The 2015 MDG report of the United Nations Secretary-General argues the need for coordination and involvement of national agencies in monitoring (see Box 3.5). Second, can these data and information systems work together across space and time? That is, can they be trusted to help social, economic and political discussions, and also withstand times of transition? Third, are they auditable? Will they stand up to scrutiny? Fourth, knowledge, statistics and data are inherently political and can create challenges to governments in the knowledge discourse.

### Underlying challenges

Major data gaps, across the globe and across environmental domains, limit our ability to identify trends and manage unwanted outcomes. In many countries, official statistics on the environment are rarely generated, are difficult to access, are scattered across different institutions, and reporting is fragmented (UNEP 2016). Across many environmental topics, data availability is geographically unbalanced, being scarcer for rural areas and developing countries. Monitoring systems from global to regional scales are fragmented, lack coverage and are often not updated on a regular basis (UNEP 2012, p. 129). There is a pressing need to create regular monitoring that follows commonly agreed international standards that are best enacted through international cooperation. There is also a need for increased sharing of data in a standardized format, for example, data that is compliant with Statistical Data and Metadata e-change standards.

The United Nations SDG report of 2016 explains that data requirements for the global indicators are almost as unprecedented as the SDGs themselves, and constitute a challenge for many countries. Tracking progress on the SDGs would require the collection, processing, analysis and dissemination of an unprecedented amount of data and statistics at the subnational, national, regional and global levels, including those derived from official statistical systems, as well as from new and innovative data sources (United Nations 2016b).

While knowledge systems often cross national boundaries, the creation, custodianship, distribution and use of knowledge have historically and politically been associated with governments. Knowledge does not exist in a geopolitical, social or economic vacuum. Will these new systems be able to inform political decision making and acceptance of environmental development and management?

### 3.7.2 Geospatial information

Environmental monitoring and forecasting systems have been growing rapidly. However, combining information from multiple systems to generate statistics and indicators remains a major challenge. Earth observation is defined by the global Group on Earth Observations as both surface observations (*in situ*) and those collected by aircraft and remote sensing, including from satellites and other space missions. Similarly, a data set collected for one purpose can often be used for multiple purposes. For example, agricultural land cover could

be useful for understanding natural disaster risk, examining the migration of people, the nature of informal settlements, urban infrastructure and their relationship with biodiversity and ecosystems.

Earth observations and environmental monitoring are being transformed through integration of administrative data from national statistical agencies, including economic data, and open data policies for Earth observations that benefit both emerging economies and developed countries. Open Earth observations, citizen science, social media, and digital platform or big data access can stimulate a transformation to a new model for creating data which results in more inclusive, social, robust knowledge for decision-making, where there is broader understanding and access to policy-relevant knowledge.

For example, the first *Atlas of the Human Planet* (Pesaresi *et al.* 2017), derived from the Global Human Settlement Layer (GHSL), provides a validated source of information on human habitations, from villages to megacities. The baseline data, spatial metrics and indicators related to population and settlements, developed in the frame of the Group on Earth Observations Human Planet initiative, provide users with a baseline data platform for monitoring and analysis. The GHSL resource is an example of the potential of public data to support global, national and local analyses of human settlements and, in particular, support policy and decision-making. This application of Earth observations is essential for evidence-based modelling of human and physical exposure to environmental contamination and degradation, as monitored through multilateral environmental agreements; disasters as encompassed by the Sendai Framework for Disaster Risk Reduction; the impact of human activities on ecosystems, as measured by the Convention on Biological Diversity; and human access to resources, assessed by the SDGs (European Commission 2018).

In September 2015, the United Nations General Assembly endorsed *Transforming Our World: The 2030 Agenda for Sustainable Development*, a global development agenda to use to monitor progress on economic, social and environmental aspects of sustainability, as stipulated in Article 76 (Box 3.5) (A/RES/70/1).

Within the United Nations system, agencies including the UNSC InterAgency Expert Working Group (IAEG-SDG) and the United Nations custodial agencies taking a lead in developing monitoring methodologies are examining, and in some cases preparing to incorporate, Earth observation and geospatial data for support of the SDGs, its targets and indicators. A 2016 analysis by the Group on Earth Observations estimated that at least 98 targets and indicators could benefit from and use

### Box 3.5: Article 76 of the 2030 Agenda

"We will promote transparent and accountable scaling-up of appropriate public-private cooperation to exploit the contribution to be made by a wide range of data, including Earth observation and geo-spatial information, while ensuring national ownership in supporting and tracking progress."

– United Nations, General Assembly (2015)

Earth observations data (United Nations 2016c). The Earth observations global community is fully engaged and ready to provide expertise to all United Nations members, particularly developing countries, with regional and specific national capacity-building.

### 3.8 Conclusion

#### ***Gender and social-environment intersectionality***

The differences in exposure to environmental problems and risks result in different perspectives for men and women, thereby reflecting unequal reaction to and interpretation of opportunities for development and sustainability. Since the environment is shaped by a blend of social identities and norms, improved collection and strengthened analysis of high-quality and timely disaggregated data by gender, age, race and other characteristics in the national contexts are required to establish a holistic baseline, and for monitoring and assessment. Such data should also be spatially disaggregated and geographically sensitive to capture local variations.

#### ***Equity and the human-environment interactions***

Collection, disaggregation and analysis of data for the most vulnerable communities remain a challenge. More work in this area would better capture issues of inequality (United Nations 2012, p. 12). Industry generally funds research that helps improve industrial processes and increase shareholder value, while philanthropists may cover a range of issues including equity issues. It is important to promote data and knowledge on how “to overcome barriers to political and social participation and to accessing services and proactive policies and sustained social communication to influence social norms that perpetuate discrimination and exclusion” (United Nations 2012, p. 9). Furthermore, in terms of regional concentration, research is concentrated geographically in the United States of America, China, Japan and Germany, which collectively account for 63 per cent of the global research and development expenditures, mostly funded by the business sector (National Science Board 2016, pp. 41-46). Businesses as funders of research have overtaken government-led funding, which has moved the balance towards more applied research than basic research (United States National Science Board 2016). This issue raises the question of who is reaping the benefits of research and if a greater good is achieved by it.

#### ***Environment and economy***

Economic evaluation of environmental impacts involves the overall assessment of nature's contributions to the lives of people; the accounting of global economic activities, investment and trade to people and the environment; and the comprehensive institutional issues affecting equity and market operations. Specific findings on sustainability can only be revealed through a robust analysis, covering ecological, social and cultural factors, and their interaction over time. Valuation

attributes a monetary values to environmental benefits and costs, as well as trade-offs and competition. Economic analysis of the environment should be oriented towards the wider scope of the SDGs, including peace, equity and security. The monetary and non-monetary values in relation to the environment and resources, as well as models reflecting the economics of nature, can only be generated through timely and reliable data and information from statistical surveys and other new data sources such as big data.

#### ***Environment and health***

Combined physical and social environments have strong influences, both direct and indirect, on human health and well-being. With this, the measurement of linkages between the ‘exposure’ and ‘outcome’, the assessment of causal relationships, and the exposure to populations need strong statistical bases and large sample sizes (i.e. big data). Challenges facing epidemiological studies include data protection, reliability and disparity when using administrative databases. Recent developments include the use of big data to allow assessment of long-term environmental exposures. It is necessary to explore the use of other sources of information to validate the long-term effects of human activities and natural disturbance such as climate change on health, with the use of new forms of data and knowledge (i.e. citizen science and traditional knowledge).

#### **3.8.1 Better data for a better planet and better lives**

The United Nations 2030 Agenda serves as the global framework for assessing economic, social and environmental development, focusing on building a healthier planet and fostering better lives through national engagement and partnerships. Monitoring the progress on the SDGs requires shifts in data collection, analysis and dissemination, including using environmental statistics, geospatial data, Earth observation and new data sources (i.e. citizen science, big data, traditional knowledge).

A new and innovative approach to data and knowledge systems with an aligned focus on evidence-based information gathering is essential for achieving the ambitious SDG framework. However, monitoring the entire SDG framework over the 2016-2030 period is estimated to cost as much as a quarter of a trillion dollars (Jerven 2014). So, in addition to improving data systems, there is also a need for priority setting to target data collection and improve efficiencies.

Environmental change is difficult to measure, and the effects of environmental change are even more complicated to measure, especially in relation to identifying causes. A shift from focusing solely on the physical dimensions to including social orientation, economic value and impacts on health and well-being is crucial but is a challenge for even well-developed statistical systems.

# Executive summary

**Environmental pollution is still a major source of damage to the health of the planet** (*well established*), **human health** (*well established*), **equity** (*well established*) and **economic sustainability** (*established but incomplete*). The risks, however, are systemic and wide-ranging, including climate change, ecosystem and biodiversity loss, wildlife damage, systemic change and other major issues. Sustainable development is possible if 'Healthy Planet, Healthy People' becomes central to our understanding of genuine progress. Solutions need to be both evidence-based and systemic, tackling sources of pollution, aiming for co-benefits and checking for unintended consequences. {4.2.1}

**The number of people affected by both slow and sudden-onset environmental disasters is increasing due to compounding effects of multiple and interacting drivers** (*well established*). These drivers include climate change and environmental degradation, poverty and social inequality, demographic change and settlement patterns, increasing population density in urban areas, unplanned urbanization, unsustainable use of natural resources, weak institutional arrangements, and policies which do not consider disaster risk. Disasters undermine human security and well-being, resulting in loss and damage to ecosystems, property, infrastructure, livelihoods, economies and places of cultural significance while forcing millions of people each year to flee their homes. {4.2.2}

**Gender equality and women's empowerment are multipliers of sustainability** (*well established*). Ensuring gender-equal representation in environmental assessments, resource management and environmental decision-making ensures that diverse experiences and knowledge systems about the environment are integrated and ecosystem conservation and sustainable use of natural resources are enhanced. In this way, increasing gender equality and women's empowerment contribute to achieving the environmental dimension of the Sustainable Development Goals (SDGs). {4.2.3}

**Significant progress has been made around the world with implementing education for sustainable development (ESD) in all educational sectors** (*well established*). However, upscaling of ESD is still needed in order to include it as a core element in the structures of educational systems globally. In this way, education will contribute to achieving the SDGs. Policies are needed that eliminate economic and gender barriers to accessing education. {4.2.4}

**Urban footprints have transboundary ramifications** (*well established*). The magnitude, scale and scope of contemporary urbanization is now so large as to be affecting global resource flows and planetary cycles. At the same time, the current urbanization process and its prospects represent not only a challenge, they also represent an opportunity to improve human well-being with potentially decreasing environmental impacts per capita and per unit of production. {4.2.5}

**Climate change is one of the most pressing issues affecting natural** (*well established*) and **human systems** (*established but incomplete*) (**SDG 13**). The evidence of current global climate change is unequivocal. Worldwide, the average surface

temperature has gone up by about 1.0°C since the 1850-1879 period; if the current rate of greenhouse gas emission persists by the 2040s warming will exceed 1.5°C. Eight of the ten warmest years on record have occurred within the past ten years. The impacts of climate change are much wider than temperature increase, affecting water availability, ecosystems, energy demand and production, transportation and other sectors. Shifts in weather patterns, extreme events (e.g. heat waves and droughts) and environmental disruptions (e.g. crop failures) result in greater risks to human health and well-being, and livelihoods, especially among the poorest and most vulnerable groups. {4.3.1}

**Current observations and climate model experiments indicate that polar surface temperatures increases exceed twice the mean global temperature rise** (*well established*). This amplified warming has cascading effects on other components of the polar-climate system, with sea ice in the Arctic retreating; permafrost thawing; snow cover extent decreasing; ice sheets decaying; and ice sheets, ice shelves and mountain glaciers continuing to lose mass, contributing substantially to sea level rise. {4.3.2}

**Modern society is living in the most chemical-intensive era in human history, the pace of production of new chemicals largely surpasses the capacity to fully assess their potential adverse impacts on human health and ecosystems** (*well established*). The risks to human health and ecosystem integrity produced by the combined effects of certain currently used chemicals, including in products, given their occurrence in the environment as a complex mixture, even in remote areas, are poorly understood and need further evaluation. Regulations, assessment and monitoring as well as industry and consumer responsibility, in informing and substituting the use of chemicals of global concern with safer alternatives are needed. Sustainable and green chemistry is aiming to achieve the sustainable design, production, use and disposal of chemicals throughout their life cycle, while taking into account the three dimensions of sustainable development. {4.3.3}

**The disposal and discharge of waste to receiving environments is negatively impacting ecosystem and human health** (*well established*). Issues of global concern include: increasing distribution and impact of marine litter, in particular plastic, in the world's oceans; the loss and wastage of approximately one-third of the food produced for human consumption; and increased trafficking of waste from developed to developing countries. While developed countries transition to reduced waste generation and greater resource efficiency, developing countries grapple with basic waste management challenges, including uncontrolled dumping, open burning, and inadequate access to waste services. {4.3.4}

**The use of resources and the environmental impacts of resource extraction and use are growing despite a large potential for resource efficiency through circular economy and sustainable consumption and production approaches** (*well established*). Global resource use has accelerated since the year 2000 and reached 90 billion tons in 2017; high-income countries consume ten times the amount of resources that

low-income countries consume; resource efficiency has been stagnant and the environmental impacts of resource use have been growing at a rate commensurate with overall resource use; there are many economically attractive opportunities for resource efficiency in the short term; in the medium and long term resource efficiency creates better economic outcomes compared with business as usual; there are considerable co-benefits of resource efficiency for climate mitigation. {4.4.1}

**Coupled with efficiency improvements, transition to low-carbon energy sources has been accelerating globally over the last decade but it is still not sufficient to achieve the 2°C target of the Paris Agreement** (*well established*), warranting bolder action in terms of technology innovation. Meanwhile the access of billions of poorer people to electricity and other modern energy services remains a challenge. {4.4.2}

**The food system is increasing local to global pressures on ecosystems and the climate** (*well established*). Farming is the most expansive human activity in the world and the principal user of fresh water. Food production is the main driver of biodiversity loss, a major polluter of air, fresh water and seawater, a leading source of soil degradation, and a significant source of greenhouse gas emissions. Changing consumption patterns are both increasing these pressures and presenting new food security challenges resulting in malnourishment, including overnourishment, as well as undernourishment. Climate change, natural resource constraints, and demographic trends suggest that the challenge of producing and distributing nourishing and sustainable food for all continues to escalate and will necessitate significant changes in food production and consumption. {4.4.3}

## 4.1 Introduction

As understanding of the interdependence between a healthy planet and healthy people becomes more developed, complex issues that thread through systems and societies gain new importance. Beyond the traditional Global Environment Outlook (GEO) themes addressing air, biodiversity, oceans, land and fresh water, this GEO-6 assessment addresses cross-cutting issues worthy of further examination. Using a systems approach, these cross-cutting issues offer entry points allowing another dimension for analysing GEO-6 themes as well as understanding the network of interconnections throughout earth and human systems. These cross-cutting issues are grouped according to shared characteristics: health, environmental disasters, gender, education and urbanization are grouped as 'people and livelihoods'; climate change, polar and mountain regions, chemicals and waste and wastewater are grouped as 'changing environments'; and resource use, energy and food systems are considered as 'resources and materials'. While each issue provides useful entry points into GEO-6 themes, it is important to discuss the state of the environment and policy context for each one.

As the deficiencies in our traditional issues-based approach to environmental assessment limit our ability to consider truly transformative pathways, cross-cutting and more integrated approaches are essential and must ultimately displace those based on single-issue analyses. Therefore, this chapter initiates a new approach in the GEO assessment process through an analysis of selected cross-cutting issues that illustrate the pressing need for more integrated and transformative policy responses. Given the global scale of the GEO-6 assessment, the chapter can address only a few cross-cutting issues, threads and influences among the myriad possible combinations. The cross-cutting issues selected for this assessment are chosen because of their close alignment with the SDGs and the fact that the scope and influence of these different issues vary dramatically over time, scale and region.

Given the obvious intersections among these cross-cutting issues, a number of emerging issues arose in regard to taking a 'Healthy Planet, Healthy People' perspective. This chapter addresses the health of the environment, the consequences for human health from pollution of all kinds, climate change impacts, environmental disasters and unsustainable consumption of natural resources, as well as the longer-term health effects of rapid and intense changes to lives, livelihoods and the environment, which require a wider focus.

The policy implications of addressing these cross-cutting issues converge on four particular human and economic systems that could accomplish the required transformation into a healthy planet supporting healthy people. Contributions from all 12-issue teams, including insights from at least 50 issue specialists from around the world, developed into system studies on climate change adaptation, sustainable food, clean energy systems and a more circular economy. The products of these collaborative efforts are presented in Chapter 17 (Part B) of this report.

## 4.2 People and livelihoods

### 4.2.1 Health

The public health community has two long-established ways of reflecting the complex web of relationships between healthy planet and healthy people that is central to GEO-6. One way is to define human health inclusively as "a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity" (World Health Organization [WHO] 1948), and then use 'well-being' (Glatzer *et al.* 2015; Maggino 2015) together with 'health' to incorporate the psychological, emotional and social dimensions. The second way focuses on the determinants of health: it recognizes that human health is mediated by multiple factors in the natural, social and built environments, including our senses of equity and safety as well as equitable access to environmental resources and human contact with nature (WHO 2008). So, while human health is the direct focus of Sustainable Development Goal (SDG) 3, this complexity links health and well-being directly and indirectly to all the SDGs (e.g. Section 20.3.1) and to issues throughout GEO-6, including the thematic chapters and other cross-cutting topics.

Buse *et al.* (2018) identify six frameworks developed from late 20th century onward to show and deal with this complexity: political ecology of health, environmental justice, Ecohealth, One Health, Ecological Public Health, and Planetary Health. These frameworks represent a shift towards a more sophisticated understanding of the implicit, complex and systemic links between human health and well-being and the natural environment. They build on an older tradition (from the mid-19th century), of 'occupational and environmental health'. This is narrower (e.g. Ayres *et al.* eds. 2010) than the more recent frameworks in two ways. First, health is often interpreted as risk of death and disease or illness, referred to as mortality and morbidity, rather than as the more holistic health and well-being. Second, it focuses on the physical, chemical and biological spheres, rather than on the social as well as determinants of health.

Within this traditional but narrow framework of pollution and disease, this report shows numerous examples of how health is damaged by environmental changes including air, water and land pollution; heat waves, flooding and other weather extremes; toxic chemicals; pathogens; ultraviolet and other radiation; desertification; reduced biodiversity; melting of polar ice; and destruction of coral reefs. Overall, "natural systems are being degraded to an extent unprecedented in human history" (Whitmee *et al.* 2015, p. 1,974) and the damage to human health is already severe. For example, the Lancet Commission on pollution and health (Landrigan *et al.* 2017) estimated that diseases caused by environmental pollution resulted in 9 million premature deaths in 2015. The biggest effects are from exposure to outdoor and indoor air pollution, which together caused 6.4 million deaths in 2015 (Cohen *et al.* 2017). More generally, the incidence of non-communicable diseases is on the rise globally and will continue to be affected by the state of the environment in relation to pollution, diet and physical (in)activity. However, human health depends on much more than a healthy planet.

Similarly, Prüss-Ustün *et al.* (2016) estimated that in 2012 modifiable environmental health risks caused 12.6 million deaths globally, representing 23 per cent (13-34 per cent, 95 per cent confidence interval [CI]) of all deaths. These are big impacts, but nevertheless they show that even if it were desirable and feasible to attain a healthy, sustainable planet without addressing socioeconomic issues and associated determinants of health, it would still leave humanity far short of the goal of 'healthy people' (see also Section 20.3.1).

Environmental pressures and their impacts on health and well-being are not equitably distributed. They fall especially on groups that are already vulnerable or disadvantaged, such as young people and elders, women, poor people, those with chronic health conditions, indigenous peoples and people targeted by racism (Solomon *et al.* 2016; Landrigan *et al.* 2017, pp. 27-31). For example, unsafe food and water can cause diarrhoeal diseases (Mills and Cumming 2016), with children under five in sub-Saharan Africa and South Asia being the most affected (Walker *et al.* 2013; Prüss-Ustün *et al.* 2014) (SDG 3 notes that four out of every five deaths of children under age five occur in these regions).

New challenges (which may be countered by relevant, sound, scientific research) include the growth of resistance of pathogens to antibiotics (antimicrobial resistance) that have been, and are, used heavily in agriculture and aquaculture (Finley *et al.* 2013; Wallinga, Rayner and Lang 2015); the multitude of industrial chemicals (though not all are widely used) that challenges our ability to meaningfully test their potential impacts on environmental and human health, including for future generations (The American Society of Human Genetics *et al.* 2011; Sharma *et al.* 2014; Landrigan *et al.* 2017); the cumulative effect (both social and environmental) of multiple exposures, including those of chemical mixtures (Solomon *et al.* 2016); emergence and re-emergence of infections originating in birds and animals (Ostfeld 2009; Lindahl and Grace 2015; Hassell *et al.* 2017); increased physical inactivity associated with new technology for work and leisure; and others including some whose effects on human health are currently unclear (e.g. the presence of microplastics in fish and marine biological resources).

Solutions to the degradation of natural systems, including the management of environmental pollution at its sources, should take account of the complex interactions between planet and health (Whitmee *et al.* 2015) and consider environment-health as a complex system, seeking co-benefits (Haines 2017), and where practicable avoiding trade-offs or win-lose situations or unintended adverse consequences (von Schneidmesser *et al.* 2015). There are now many examples of health co-benefits, especially of greenhouse gas reductions (Chang *et al.* 2017; Quam *et al.* 2017; Deng *et al.* 2018). For example, the unfolding transition to cleaner energy improves air quality and slows climate change effects, each of which greatly benefits health and well-being (Smith *et al.* 2014a; Haines 2017; see also Section 4.2.1). Active travel, such as walking and bicycling, can have multiple benefits for health and well-being (Saunders *et al.* 2013; Smith *et al.* 2014a); however, benefits will vary with (for example) climate and pollution levels. Reducing red meat intake per capita where there is high consumption, especially of processed meat, will improve human health (McMichael *et al.* 2007; Wolk 2017), while reducing pressure on biodiversity and

greenhouse gas emissions, including methane. The benefits to human health and well-being of access to safe and biodiverse natural environments, green and blue spaces, are being recognized (Coutts and Hahn 2015; Wolf and Robbins 2015; Wall, Derham and O'Mahony eds. 2016; Grellier *et al.* 2017).

Rigorous incorporation and integration of human health considerations within health-determining sectoral plans (e.g. agriculture, water, disaster management, urban design) can support responses that address human health impacts, with a focus on prevention activities. Initiatives to reduce environmental risks, focusing on benefits across sectors, are consistent with the World Health Organization's (WHO) call for Health in All Policies (WHO 2014) and the development of tools for integrated environmental and health assessment (Fehr *et al.* 2016). The health sector must rapidly strengthen the way that it articulates messages on human health and emphasize that the majority of environmental pressures will ultimately have human health impacts.

More fundamental changes may be needed, for example "the redefinition of prosperity to focus on the enhancement of quality of life and delivery of improved health for all, together with respect for the integrity of natural systems" (Whitmee *et al.* 2015). This view resonates with intentions to keep the GEO-6 goal of Healthy Planet, Healthy People central to our understanding of genuine progress.

#### 4.2.2 Environmental disasters

Hazards become disasters when they disrupt human communities. Therefore, the consequences of these disasters are as much a part of where and how people live as the presence of the hazard itself (Sun 2016, p. 30). This includes anthropogenic effects on the climate, but also disasters directly caused by human activities such as oil spills, accidents at nuclear power stations or other hazardous installations, and even earthquakes triggered by fracking and the building of large dams (Legere 2016). Sudden-onset disasters, such as earthquakes, tsunamis, landslides, flash floods and severe storms, are distinguished from slow-onset events, experienced as drought, desertification, sea level rise and coastal erosion. Slow-onset events comprise as much as 90 per cent of disasters worldwide and threaten growth, development and livelihoods (Lucard, Jaquemet and Carpentier 2011). Development and disaster risk are closely linked; decisions regarding the management of natural resources and development pathways determine patterns of vulnerability and exposure to a range of environmental hazards. Disasters, in turn, can set back development gains by years or even decades, at immense social and economic cost. Over the long or short term, these decisions and their management can act as drivers of migration and displacement (United Kingdom Government Office for Science 2011). They can also affect peace and security (Schilling *et al.* 2017).

Environmental disasters are affecting an increasing number of people globally and taking an ever-larger toll on societies and economies, particularly in the poorest communities and countries. Between 2005 and 2015, they affected more than 3 billion people (Centre for Research on the Epidemiology of Disasters 2017). This is partly due to an increase in frequency and magnitude of climate and hydrometeorological hazards

**Figure 4.1: The economic and human impact of disasters in the last ten years**

Source: United Nations Office for Disaster Risk Reduction (UNISDR) 2014

such as tropical cyclones, fires and floods. However, social and economic processes that increase exposure to hazards by placing more people, infrastructure and economic activities in harm's way significantly escalate disaster risk. For example, migration away from rural drought to overcrowded, poorly planned, coastal megacities in flood-prone zones can increase mortality, displacement, health and disaster risks in urban areas.

In some cases, disasters result from the combined effect of several interacting hazard events. The 2011 Tohoku disaster in Japan exemplified such a case when a sequence of cascading events occurred, including an earthquake, a tsunami and a nuclear power plant accident, all contributing to 15,893 casualties. The disaster forced more than 350,000 people into protracted displacement (i.e. displacement of more than one year) and cost an estimated US\$ 210 billion in direct damage. Disasters also disproportionately affect some of the most vulnerable populations; 54 per cent of fatalities from the Tohoku disaster were women and girls, and 56 per cent were above age 65 (Leoni 2012). To date, it remains the most expensive environmental disaster in history (Ranghiere and Ishiwatari eds. 2014, pp. 2, 269, 284).

The consequences of disasters are far-reaching and long lasting. In 2016 alone, 24.2 million people in 118 countries became newly internally displaced by sudden-onset disasters (Internal Displacement Monitoring Centre [IDMC] 2017, p. 10). They outnumbered those who were newly displaced by conflict and violence three to one (IDMC 2017). Precipitation shocks, droughts, floods and storms in Philippines, for example, correspond with significant intensifications of conflict

(Eastin 2016, p. 12). The Protection Agenda of the Nansen Initiative, endorsed by 109 governments in 2015, is a key instrument to foster the protection of the rights of those displaced across borders by disasters. The Platform on Disaster Displacement, established in 2016, is tasked with supervising implementation of the Agenda and following up on the work carried out by the Nansen Initiative between 2012 and 2015 (Disaster Displacement 2017). In many cases, drivers of displacement are difficult to disentangle from other destabilizing factors. The African Union's Kampala Convention, a legally binding protection instrument shielding those displaced by conflict, violence and human rights abuses alongside disasters, is an important step in recognizing these interactions (African Union 2009).

Learning from past disasters and shifting from a culture of disaster response to one of prevention, preparedness and resilience is imperative. While initiatives such as disaster response and recovery strategies have been formulated in many countries following disaster events, the number of countries that have incorporated prevention, mitigation and preparedness as part of a comprehensive disaster risk reduction strategy remains quite low (Ranghiere and Ishiwatari eds. 2014, p. xv). The Sendai Framework for Disaster Risk Reduction 2015-2030 (UNISDR 2015) represents a new opportunity to further improve disaster risk reduction efforts. Improvements can be achieved by mobilizing and prioritizing investments, enhancing policy and institutional coherence, promoting innovation and technological development, increasing collaboration and cooperation, and mainstreaming disaster risk reduction in development and climate change adaptation efforts.

### 4.2.3 Gender

A gender approach redefines the environmental situation through the lens of social relationships and their reflection in human-environment interactions, instead of defining the state of the environment primarily in its physical or ecological forms. Gender analysis reveals that while systemic environmental problems typically manifest in physical landscapes and ecosystems, the state of the environment can only be explained by examining social, cultural and economic systems and arrangements. Those structures are 'gendered': they are shaped by socially constructed roles and relationships between women and men. For example, in *The State of Food and Agriculture 2010-11* paragraph 4.3.3 on 'Food systems' the role of women in agriculture is underlined (Food and Agriculture Organization of the United Nations [FAO] 2011).

**Figure 4.2** shows that women's and girls' responsibilities in collecting water is much larger than that of men and boys (United Nations Entity for Gender Equality and the Empowerment of Women [UN-Women] UN Women 2015; Sagrario and Willoughby 2016; United Nations Environment Programme [UNEP] 2016a; WHO 2017).

Assessments of the economic value of environment-related sectors are often seriously distorted because women's contributions are overlooked (see also Section 4.1.3). For example, the economic work of women in fisheries continues to be undercounted, partly because fishing is often defined only as catching fish at sea with specialized equipment. This type of fishing is highly masculinized (Harper *et al.* 2013; UNEP 2016a; Harper *et al.* 2017). Women's tasks in the fishing sector focus on coastal fishing, fish processing and trade, and are often

**Figure 4.2: Percentage distribution of the water collection burden across 61 countries**

Source: UNICEF and WHO (2017, p. 30).

neglected (Lambeth *et al.* 2014). Throughout this publication, some other examples of the gender-environment relationship are included.

The scholarly and practitioner field of gender and environment has been developing since the 1980s and is now a large and robust domain of analysis and assessment (Skinner 2011; Aguilar, Granat and Owren 2015). Early directions in this field focused on identifying the gender-differentiated impacts of environmental change (Dankelman and Davidson 1988). Now, an emerging focus is examining the ways in which the drivers of environmental change are also gendered, rooted in socially constructed norms of masculinity and femininity, including in our economies, sciences and technologies (Harcourt and Nelson eds. 2015; UNEP 2016a). Revealing the gendered dimensions of environmental dynamics illuminates new aspects of environmental states and trends, as well as pointing out pathways for transformations and policy solutions that are sustainable. The Global Gender and Environment Outlook, which elaborates on the importance of gender in most environmental areas, provides the first comprehensive global assessment of the gender-environment nexus and offers a channel for gender analysis in GEO-6 (UNEP 2016a). Applying a gender lens to environmental assessment also creates awareness of the relevance of additional social dimensions and intersections in environmental use and management, such as differentiation by class, race or ethnicity, caste and age (Harris 2011).

Recent studies recognize the diverse roles of men and women in collecting forest products and their related diverse knowledge systems (Sunderland *et al.* 2014; Chiwona-Karlton *et al.* 2017). Evidence from studies on community forest management point to the understanding that women's participation in environmental assessment and resource management can enhance ecosystem conservation and sustainable use of natural resources (Agarwal 2010; Agarwal 2015).

Other evidence suggests that when women are accorded equal voice in environmental decision-making, public resources are more likely to be directed towards human development priorities and investments (Chattopadhyay and Duflo 2004; UN-Women 2014). Women's enhanced access to and control over productive agricultural resources helps create food security and sustainable livelihoods (FAO 2011; UN-Women 2014). The use of gender budgeting is another important approach to promote gender-responsive financing. The SDG framework reveals that sustainable development will not evolve, nor will environmental policies and initiatives be effective, if gender equality and women's empowerment are not enhanced (United Nations 2015a). Environmental sustainability and justice contribute significantly to SDG 5: achieving gender equality and empowering all women and girls, and to the gender targets of SDGs 1, 4, 8 and 10 (Agarwal 2010; UNEP *et al.* 2013; Agarwal 2015; United Nations 2015b; Dankelman 2016; UNEP 2016a). While gender equality can be tacitly read in all the other SDG goals, there are almost no explicit gender targets and indicators included in the environment-related SDGs.

Bringing gender perspectives to bear on environmental frameworks is not a matter of simply adding 'women' into environmental analyses. Approaching the environment through a gender lens means new and different questions in environmental assessment, emphasizing different dimensions of human-environment relationships and requiring gender-

responsive methodological tools and approaches, as well as gender-disaggregated data (Patt, Dazé and Suarez 2009; Doss 2014; Seager 2014; Bradshaw and Fordham 2015; Harcourt and Nelson eds. 2015; Jerneck 2018). Given the difficult state of the environment, the persistence of drivers of environmental change, and the severity of societal and ecological consequences that societies face, a gender-integrative approach is a precondition for more effective and transformative environmental policies and interventions.

#### 4.2.4 Education

Education for Sustainable Development (ESD), a key area of education, reaching gender equality, developing healthier and more sustainable lifestyles, and creating more peaceful societies. However, this requires access to education for all and a high quality of education (United Nations Development Programme [UNDP] 2016; United Nations Educational, Scientific and Cultural Organization [UNESCO] 2017a). Despite all efforts to provide all children worldwide with access to education, this is still not a reality for all children. "Worldwide, 91 per cent of primary-school-age children were enrolled in school in 2015" (UNICEF 2018). "In 2015, there were 264 million primary and secondary age children and youth out of school: 61 million children of primary school age (9% of the age group), 62 million adolescents of lower secondary school age (16%), and 141 million youth of upper secondary school age (37%)" (UNESCO 2017a, p. 118). Also gender equality is still a major challenge: "While there is gender parity in education participation, global averages mask gaps between countries: only 66% have achieved gender parity in primary education, 45% in lower secondary and 25% in upper secondary" (UNESCO 2017a, p. 182). Education for Sustainable Development, a key area of education, aims to enable individuals to contribute to fostering sustainable development. Instead of promoting certain behaviours and ways of thinking (instrumental approach), an emancipatory concept of ESD concentrates in particular on the critical reflection on expert opinions, testing possibilities of sustainable development and exploring the trade-offs of a sustainable lifestyle (Wals 2015; UNESCO 2017b; Rieckmann 2018). It aims to empower individuals to act responsibly in order to contribute to the creation of sustainable societies, and to prepare them for disruptive thinking and the co-creation of new knowledge (Lotz-Sisitka *et al.* 2015; UNESCO 2017b), but also for exploring and using traditional and indigenous knowledge.

With the overall aim to develop cross-cutting sustainability competencies within learners (Wiek, Withycombe and Redman 2011; Rieckmann 2018), ESD is an important contribution to achieving the SDGs: it enables all people to contribute to achieving the SDGs by providing them, not only with the knowledge to understand what the SDGs are all about, but also the competencies to make a difference towards a more sustainable society (UNESCO 2017b).

The emancipatory ESD approach asks which key competencies are needed for learners to be 'sustainability citizens' (Wals and Lenglet 2016). Various key competencies essential to sustainable development have been outlined (e.g. Wiek, Withycombe and Redman 2011; Rieckmann 2012; Glasser and Hirsh 2016; Wiek *et al.* 2016) – describing what individuals need to be able to do to transform their own individual lifestyles to more sustainable ones and to contribute to societal transformation towards sustainability. In the international

ESD discourse, there is agreement that the following key competencies are of particular importance for thinking and acting in favour of sustainable development (UNESCO 2017b; Rieckmann 2018):

- ❖ Systems thinking competency
- ❖ Anticipatory competency
- ❖ Normative competency
- ❖ Strategic competency
- ❖ Collaboration competency
- ❖ Critical thinking competency
- ❖ Self-awareness competency
- ❖ Integrated problem-solving competency

However, while competencies describe the capacity or disposition of acting, they do not necessarily imply that an individual will act in a certain way in a specific situation. Sustainability-oriented performance depends on the interplay of knowledge and skills, values and motivational drivers, and opportunities (Biberhofer *et al.* 2018). The interrelation of these dimensions influences personal behaviour (Figure 4.3).

ESD is directly related to the other cross-cutting issues. It enables people, for example,

- ❖ "to act in favour of people threatened by climate change", and "to promote climate protecting public policies" (UNESCO 2017b, p. 36);
- ❖ "to develop a vision of a reliable, sustainable energy production, supply and usage in their country", and "to apply and evaluate measures in order to increase energy efficiency and sufficiency in their personal sphere and to increase the share of renewable energy in their local energy mix" (UNESCO 2017b, p. 24);
- ❖ "to communicate the need for sustainable practices in production and consumption", and "to challenge cultural and societal orientations" (UNESCO 2017b, p. 34);
- ❖ "to reflect on their own gender identity and gender roles", and "to plan, implement, support and evaluate strategies

**Figure 4.3: Key competencies and performance of sustainability citizens**

Source: Rieckmann (2018).

- ❖ for gender equality” (UNESCO 2017b, p. 20); and
- ❖ “to encourage others to decide and act in favour of promoting health and well-being for all”, and “to include health promoting behaviours in their daily routines” (UNESCO 2017b, p. 16).

ESD is at the heart of teaching and learning and should not be seen as a complement to the existing curriculum. “Mainstreaming ESD requires integrating sustainability topics into the curricula, but also sustainability-related intended learning outcomes” (UNESCO 2017b, p. 49). Since sustainability competencies cannot be taught or conveyed, but can only be developed by the learners themselves, an action-oriented transformative pedagogy is required (Mindt and Rieckmann 2017; UNESCO 2017b; Rieckmann 2018). In addition to the formal education curricula, ESD should also be promoted by non-formal and informal education. Community engagement and local learning can also play an important role, especially for involving traditional and indigenous knowledge into the learning process.

During the United Nations Decade for Education for Sustainable Development (2005-2014) (DESD) significant progress was made around the world with implementing ESD in all educational sectors (e.g. McKeown 2015; Watson 2015). Monitoring and evaluation of the DESD has shown many good examples of integrating ESD in curricula. Reviews of official curriculum documents show that “many countries now include sustainability and/or environmental themes as one of the general goals of education” (UNESCO 2014, p. 30). Most progress has been made in developing curricula towards ESD in primary and secondary education. “Close to 40% of Member States indicate that their greatest achievement over the DESD has been the integration of ESD into formal curricula, with another fifth describing specific school projects as being their most important contributions to ESD” (UNESCO 2014, p. 82). There has also been good progress with the implementation of ESD in higher education (Karatzoglou 2013; Lozano *et al.* 2015). This is particularly the case in Europe, where there has been a stronger interest in the integration of sustainable development in higher education institutions than in other parts of the world (Lozano *et al.* 2015; Barth and Rieckmann 2016).

However, upscaling of ESD is still needed in order to include it as a core element in the structures of educational systems (Singer-Brodowski *et al.* 2018). The Global Action Programme on Education for Sustainable Development, which was launched in 2014 at the UNESCO World Conference on ESD in Aichi-Nagoya, Japan, has five priority areas:

1. advancing policy;
2. transforming learning and training environments;
3. building capacities of educators and trainers;
4. empowering and mobilizing youth; and
5. accelerating sustainable solutions at local level.

It strives to scale up ESD, building on the DESD (Hopkins 2015; Mickelsson, Kronlid and Lotz-Sisitka 2018). Of particular importance in this context is the increased integration of ESD into (pre-service and in-service) teacher education. “Efforts to prepare teachers to implement ESD have not advanced sufficiently. More work still needs to be done to reorient teacher education to approach ESD in its content and its teaching and learning methods” (UNESCO 2017b, p. 51). For achieving

this reorientation of teacher education towards sustainable development, it is necessary to form strategic institutional alliances among national, regional and local governments, non-governmental organizations, universities and other educational institutions involved in teacher education. Further challenges for scaling up ESD are:

- ❖ integrating ESD in policies, strategies and programmes;
- ❖ integrating ESD in curricula and textbooks;
- ❖ delivering ESD in the classroom and other learning settings;
- ❖ and changing the ways ESD learning outcomes and the quality of ESD programmes are assessed (UNESCO 2017b).

In order for all learners to benefit from ESD and to develop sustainability competencies, policies are needed that eliminate economic and gender barriers to access to education.

#### 4.2.5 Urbanization

As explained in Section 2.3, urbanization is a major driver shaping the economy, the environment, the planet and human well-being worldwide. About 54 per cent of the world's population lives in urban areas that collectively generate more than 80 per cent of the world's gross domestic product (GDP) (United Nations Human Settlements Programme [UN-Habitat] 2011; UN-Habitat 2016a). By the year 2050, about 6.7 billion people – some 66 per cent of the world total population of 9.7 billion – are expected to be living in cities, adding 3.1 billion to cities' populations over the short span of about 40 years (United Nations 2018). While all world regions (except polar regions) will continue to urbanize, 90 per cent of future urban population growth is expected to occur in Africa and Asia (UN-Habitat 2014).

Cities are centres of innovation and historically they experience economies of scale with GDP increasing linearly with city population numbers (Bettencourt 2013). This capacity for innovation and wealth-generation, enabled by proximity and activity-intensity, is one of the features that attracts migrants to cities (International Organization for Migration [IOM] 2015), and will lead to an expansion of urban population by 2050 (Figure 4.4). However, the wealth of cities is not distributed equally across the globe, with only 600 cities contributing more than 62 per cent of the global GDP (UN-Habitat 2011).

There is also significant inequality within cities, with a staggering 2 to 3 billion people – 35 to 50 per cent of the urban population in 2050 – expected to be living in informal settlements (UN-Habitat 2014; UN-Habitat-2016a; UN-Habitat 2016b). Urbanization is associated with lower fertility rates, longer life expectancy, and better access to basic physical infrastructure and social amenities such as education and health care. However, inequality, crime and social exclusion are becoming characteristics of many urban areas, where living conditions are deteriorating in relation to the rural origins of many migrants (United Nations 2014).

Cities face huge challenges regarding social inclusion and improved provisioning of basic physical services. Energy, water, buildings, transportation and communication, food, public spaces and waste management emerge as key factors that shape the effect of cities on people, the environment and the planet.

The magnitude, scale and scope of contemporary urbanization is now so large as to be affecting global resource flows and planetary cycles. Urbanization is affecting the entire planet, not solely the areas defined as urban. Through networks of trade, migration and infrastructure, cities are influencing the natural environment well beyond their administrative

boundaries (Wiggington *et al.* 2016). For example, although directly occupying only 3 per cent of the world's land area, energy supply to cities contributes more than 70 per cent of the world's energy-related carbon emissions (Seto *et al.* 2014). Direct water supply to cities puts pressure on 42 per cent of the world's watersheds (McDonald *et al.* 2014). In addition, water embodied in food supplied to cities exceeds direct water requirements in urban areas by more than a factor of ten (Ramaswami *et al.* 2017).

Urban footprints that represent both the bounded and transboundary ramifications that cities have on natural resources and the environment are essential to characterize the consequences of different urban activities, such as household consumption, production and community-wide infrastructure provisioning, and to chart pathways towards a sustainable future. In some regions, urban areas are de-densifying: urban population growth at declining densities leads to urban land expansion, which, in ecologically sensitive regions, can cause habitat fragmentation and contribute to large-scale biodiversity loss (Seto, Guneralp and Hutyra 2012).

Cities also face management and technological transformative opportunities. Around 60 per cent of the urban area required to accommodate the urban population of 2050 is yet to be built (Secretariat of the Convention on Biological Diversity [SCBD] 2012). Once built, it will last for at least the next 40 years. The bases of urban structures (e.g. street networks, blocks) "can affect and lock in energy demand for long time periods" (Seto *et al.* 2016).

At the same time, existing cities in advanced economies are repairing or replacing ageing infrastructures. Several infrastructural innovations are on the horizon in cities of both developed and developing countries that can enhance equity, resource efficiency and environmental sustainability. These innovations include new strategies for shared mobility, *in situ* slum rehabilitation, a One-Water approach to urban water management, urban-industrial symbiosis based on sustainable production and consumption through a circular economy, electric and autonomous vehicles for mass transit and private trips, and distributed renewable energy to achieve a decarbonized and resilient grid. Cities around the world are experimenting with infrastructure involving technology, human behaviour, financing and novel governance arrangements. This provides a historic opportunity and the imperative to build inclusive and sustainable infrastructure (UNEP 2013a). Successful urbanization relies on human as well as infrastructural assets.

Urban areas will continue to act as generators of economic growth and, through fertility and migration, they will continue growing in population and size. This can result in increased impacts of cities, but also in potential decreases in impacts per unit of production and per capita. As stated in the Section 2.3 of this report, there are clear challenges and opportunities that urgently need to be understood and addressed. These are related as much to governance as to technology, as is highlighted in Part B of this report (UNEP 2017).

## 4.3 Changing environments

### 4.3.1 Climate change

As explained in Section 2.7, climate change is driven by modifications in atmospheric composition due to land-use change, primarily deforestation, and to greenhouse gas (GHG) emissions, such as CO<sub>2</sub> emitted through fossil fuel burning and methane released from agriculture and other sources, as well as the emissions of aerosol particles (Vaughan *et al.* 2013). The evidence of current global climate change is unequivocal (Vaughan *et al.* 2013).

Eight of the ten warmest years on record have occurred within the past decade (United States National Oceanic and Atmospheric Administration [NOAA] 2018). Within this period, 2016 was the warmest year in the history of instrumental observation (NOAA 2017), and 2017 was the warmest year without an El Niño influence (NOAA 2018). As a result, global warming has reached approximately 1.0±0.2°C above the pre-industrial level (Figure 4.5, Haustein *et al.* 2017; Yin *et al.* 2017).

The current GHG emission rate, if it persists, will result in continuation of the current rate of global temperature increase of ~0.2°C per decade (e.g. Haustein *et al.* 2017), crossing the 1.5°C Paris Agreement target by the 2040s (Leach *et al.* 2018). While not unattainable, the goal of limiting warming to 1.5°C requires transformational changes leading to radical reduction of GHG emissions and expedited transition to carbon neutrality (Schellnhuber, Rahmstorf and Winkelmann 2016), that requires balancing of remaining anthropogenic CO<sub>2</sub> emissions with anthropogenic CO<sub>2</sub> removals.

Climate change modifies the water cycle by altering precipitation patterns and seasons. In general, dry areas are becoming drier, and wet areas are becoming wetter (Trenberth 2011;

Intergovernmental Panel on Climate Change [IPCC] 2014; Feng and Zhang 2015), but numerous exceptions exist. Additionally, the increased water-holding capacity of warmer air leads to more extreme rainstorms that arrive less frequently (Trenberth 2011). Higher temperatures increase evapotranspiration rates and shift precipitation from snow to rain. A warmer atmosphere also governs the growth, melt and discharge of glaciers (Bliss, Hock and Radić 2014). These hydrological modifications determine river flows and the risks of early spring flooding and summer drought (Seneviratne *et al.* 2012; Cook *et al.* 2014; Kundzewicz *et al.* 2014). Changes in flow patterns alter water availability and, at the same time, higher temperatures increase demands from and competition among agricultural, industrial and domestic users (Hanjra and Qureshi 2010; Jiménez-Cisneros *et al.* 2014).

Oceans play an important role in climate regulation, having stored 93 per cent of the additional heat absorbed by the earth system since 1955. During that period, land has taken up 3 per cent of the heat absorbed, ice another 3 per cent, and the atmosphere only 1 per cent (IPCC 2013; Levitus *et al.* 2012). Heat-induced expansion of ocean water contributes to the observed sea level rise that has been accelerating over the past two decades; this trend will continue into the future even if the warming is limited to 1.5°C (Schewe, Levermann and Meinshausen 2011). Higher sea levels increase risks from storm surges for vulnerable small islands, coastal communities and exposed infrastructure. Oceans also absorb CO<sub>2</sub> from the atmosphere. Estimates suggest that, of all the CO<sub>2</sub> released to the atmosphere from human activities since the beginning of the industrial era, approximately 40 per cent has been absorbed by oceans (IPCC 2013; Khattiwala *et al.* 2013), resulting in a reduction of seawater pH (acidification), referred to as 'the other CO<sub>2</sub> problem' (Caldeira and Wickett 2003; Doney *et al.* 2009). This ocean acidification combines with warmer water temperatures and de-oxygenation processes to alter ocean

**Figure 4.5: Global annual average temperature anomalies (relative to the long-term average for 1981-2010). Labelling designates different data sets; for explanation refer to the source**

Source: United Kingdom Government Met Office (2018)

ecosystems (Achterberg 2014), most visibly as coral bleaching (see Chapter 7) when symbiotic algae are expelled from the reefs, reducing or ending their productivity (Fabry *et al.* 2008).

Estimates suggest that approximately 20 per cent of fossil-fuel CO<sub>2</sub> emissions are absorbed by land ecosystems (Arnell *et al.* 2017). Increased concentrations of CO<sub>2</sub> in the atmosphere may eventually benefit some C<sub>3</sub> crops<sup>1</sup>, a category that includes wheat and beans, through carbon fertilization (McGrath and Lobell 2013). Warmer temperatures could bring yield gains in high-latitude regions, if soil and precipitation characteristics are suitable (IPCC 2014). Seventy per cent of global agriculture is rain-fed, and shifting rainfall patterns may benefit certain regions, but higher temperatures generally cause water stress that limits yields (Lobell, Schlenker and Costa-Roberts 2011; Challinor *et al.* 2014). Despite potential local yield increase, at a global level, yields are expected to suffer due to elevated risks from droughts and heat stress (Schlenker and Roberts 2009; Lobell and Gourdji 2012; Jiménez-Cisneros *et al.* 2014; Porter *et al.* 2014). Additionally, climate change, together with direct effects of rising atmospheric CO<sub>2</sub> concentration, has also been demonstrated to benefit invasive plant species (Ziska and Dukes eds. 2014).

Climate change also affects forest productivity, including increased stress from droughts, wildfires, insects, pathogens and windstorms (Williams *et al.* 2013; IPCC 2014). However, the influence of carbon fertilization on forest productivity is not well understood given the complexity of contributing factors (Norby *et al.* 2016). In combination with other human pressures, such as habitat destruction, climate change affects biodiversity at genetic, species and ecosystem levels. Seasonal changes can disrupt the timing of gestation, birth, hibernation, resource availability and optimal productivity. Species that are able are shifting their ranges, patterns and interactions on land, in fresh water and in oceans (IPCC 2014). There are possible shifts in infectious disease distributions in flora, fauna and humans (Lafferty 2009).

The shifts in weather patterns and extreme events, such as heat waves and droughts, and environmental disruptions, including crop failures, result in greater risks to human health and survival, especially among the poor and most vulnerable groups (Smith *et al.* 2014b). Climate change is also affecting the toxicity, environmental fate and behaviour of chemical toxicants by modifying physical, chemical and biological drivers of partitioning between the atmosphere, water, soil/sediment and biota, wet/dry deposition, and reaction rates with a potential of adverse impacts on biodiversity and human health (Noyes *et al.* 2009). Recent studies have examined the link between climate change and poverty in developing countries. In general, rural households in developing countries depend on crops, forest extraction and other income sources for their livelihoods, which tend to be extremely sensitive to climate change (Wunder, Noack and Angelsen 2018). The poor are more exposed to extreme climate conditions and experience greater rainfall fluctuations, while the poorest in dry regions experience the greatest forest loss (Angelsen and Dokken 2018). Poor people are often disproportionately exposed to droughts and floods, particularly in urban areas, and in many countries in Africa (Winsemius *et al.* 2018). Poorer households

tend to be located in hotter locations within hot countries, and poorer individuals are more likely to work in occupations with greater exposure to increased temperatures across and within countries (Park *et al.* 2018). It is expected that by the end of the century global labour productivity may be reduced by 40 per cent (Dunne, Stouffer and John 2013).

The climate continues to change and the impacts on the natural and human system are increasingly recognized. Social responses such as population migration and displacement exacerbate health risks and threats to geopolitical stability (Adger *et al.* 2014); these risks increase with continuing warming beyond 1.5°C as detailed in chapters 3 and 5 of the IPCC 1.5°C report (IPCC 2018). Limiting the observed warming trend to 1.5°C requires transformational changes in policies, technologies and societal goals.

### 4.3.2 Polar regions and mountains

Covering approximately 20 per cent of the Earth's surface and containing the ice sheets of Greenland and Antarctica, the polar regions play a significant role in the global climate system. Land and sea ice not only regulate the energy balance of the climate system due to their high albedo, or reflectivity, but also store a record of climate information. In addition to their role as engines of global climate processes, the Arctic and Antarctic act as bellwethers of climate change because warming is amplified at their high latitudes (Taylor *et al.* 2013). Warming is also amplified at high altitudes, so mountain regions can be included in this discussion as a 'third pole' (Pepin *et al.* 2015).

Amplified warming affects all components of the polar climate system. Arctic Sea ice is shrinking in area and volume (**Figure 4.6**). Permafrost is thawing resulting in a release of greenhouse gases, including CO<sub>2</sub>, and snow cover extent is decreasing. Ice sheets and mountain glaciers continue to lose mass, contributing significantly to sea level rise that threatens coastal regions at every latitude (Vaughan *et al.* 2013). These transformations have consequences for polar and high-altitude ecosystems and for the people who live there. Shifting environmental and socioeconomic conditions in the Arctic in particular are delivering consequences to environments and populations further south through teleconnections within the climate system (Francis, Vavrus and Cohen 2017) and through close geopolitical connections. In fact, polar regions are gaining politico-strategic importance. The Arctic has already been subjected to resource extraction and exploitation, from hydrocarbons to diamonds (Dodds 2010; Ruel 2011), and the Antarctic is becoming an area of strategic interest for countries looking at potential resource extraction in the future. At the same time, the Arctic and particularly the Antarctic, which has a treaty devoting the continent to peace and scientific cooperation, are regions of peaceful international coordination and enhanced environmental cooperation, exhibiting governance systems that can be exemplars for environmental protection in other regions.

The ecosystem services of the polar regions that relate to global climate regulation are further enhanced by the formation of super-dense Antarctic bottom water, and to a lesser extent of North Atlantic deep water, which are significant contributors to the thermohaline circulation. The cooler ocean waters of higher latitudes, especially the Southern Ocean, also represent important carbon sinks and areas of high marine productivity.

<sup>1</sup> The plants that utilize C3 photosynthesis (85% of all plants) have disadvantage in hot, dry conditions. C3 crops include wheat, rice, soybeans, and many others.

**Figure 4.6: Arctic sea ice age and extent**

Source: United States National Snow and Ice Data Center (2017).

They play a significant role in food production in the high latitudes and require careful management through agencies such as the North Atlantic Fisheries Organization and the Commission for the Conservation of Antarctic Marine Living Resources. Some high-latitude fisheries have been significantly affected by fishing activities in the last century as highlighted in the collapse of the Atlantic cod fishery (Villasante *et al.* 2011).

More than 70 per cent of the planet's fresh water is locked up in ice in the polar regions. If released, the water stored in the Greenland Ice Sheet would result in a 7.4 metre rise in sea level, the water in the Antarctic Ice Sheet would result in a 58.3 metre rise, and the water stored in all mountain glaciers would yield a 0.4 metre rise (Vaughan *et al.* 2013). In a scenario limiting temperature increase to below 2°C, the world would still see a mean rise of global sea levels by 0.4 to 0.6 metres. A business-as-usual scenario produces an average sea level rise of 0.7 to 1.2 metres by the end of the 21st century (Horton *et al.* 2014). As the latest IPCC report and multiple independent scientific studies indicate, mountain glaciers and polar ice sheets are already losing mass and are contributing on average the equivalent of 1.85 mm of sea level rise per year (Bamber *et al.* 2018).

As more fresh water is transported to the ocean from seasonal permafrost thaw, iceberg calving, glacier and ice sheet melt, and other fluvial discharge, the increase of silt, carbon and other nutrients will affect the polar regions'

primary productivity in the marine food chain. The source and quality of food for higher organisms will shift, with much less primary productivity originating from ice-related algae, so that species at higher trophic levels, such as krill and fish, will be challenged (Alsos *et al.* 2016; Frey *et al.* 2016). This, combined with invasive species shifting into newly tolerable conditions and their potential threats, requires humans to adapt to new economic and cultural livelihoods and may result in conflicts, especially with regard to resource use, governance, cultural concerns and marine protected areas (Conservation of Arctic Flora and Fauna [CAFF] and Protection of the Arctic Marine Environment [PAME] 2017). Nearly all of the world's glaciers are losing mass and some will vanish in the coming decades (Kaltenborn, Nellesmann and Vistnes eds. 2010; Vaughan *et al.* 2013). More than a billion people rely on mountain glaciers for water, with the majority of these people living in Asia, which has around 100,000 km<sup>2</sup> of glaciers (Yao *et al.* 2012). Over 200 million people rely on water from the Hindu Kush Himalayan mountains with hundreds of millions more people downstream who are affected by reduced reliability of local water sources and increased hazards, including glacial lake outburst floods. Run-off is expected to decrease until 2050 in the Ganges, Brahmaputra and Mekong basins. At the same time, the Hindu Kush Himalaya region can expect higher variability in water flows and more water in pre-monsoon months leading to more floods and droughts. The Andes are already experiencing less run-off. Changes in temperature and precipitation will affect agriculture, water resources and health (Shrestha *et al.* eds. 2015).

Further adjustment to new realities will warrant responses to increasing levels of contaminants that have been transported long distances and accumulate in the polar regions. Despite few local industrial sources, persistent environmental contaminants were detected decades ago in these remote locations and pose significant threats to local people and environments through polar food chains (Andrew 2014). Sea-ice melting will result in air-water exchange of persistent organic pollutants in areas of the Arctic that are no longer covered with ice. Likewise, melting of polar and alpine glaciers, ice sheets and shelves, and permafrost will also release persistent organic pollutants and mercury, enabling further air-soil exchange of these pernicious compounds (Arctic Monitoring and Assessment Programme [AMAP] 2015; Sun *et al.* 2017). Due to new regulations, the levels of many persistent organic pollutants are now declining, but new chemicals are a cause for increased concern, such as organophosphate-based flame retardants, phthalates, some siloxanes, and some currently used pesticides (AMAP 2017). Equally, microplastics have now been detected in all of the world's oceans (Thompson *et al.* 2004; Browne *et al.* 2011), including in deep-sea sediments (Barnes, Walters and Gonçalves 2010) and even in Arctic sea ice (Thompson *et al.* 2004; Browne *et al.* 2011; Ivar do Sul and Costa 2014; Obbard *et al.* 2014; Isobe *et al.* 2017; Waller *et al.* 2017). More research is needed to trace the distribution and impact of microplastics in the Antarctic, but their existence in the Southern Ocean (Isobe *et al.* 2017; Waller *et al.* 2017) and in the Ross Sea (Cincinelli *et al.* 2017) has already been confirmed.

Those who live at high latitudes and in mountain regions are vulnerable to the compounding effects of air pollution, and-use changes and other factors, as well as the threats from climate change. However, people in these areas, especially the indigenous peoples who have inhabited the Arctic and mountain regions for millennia, have a rich knowledge about their environment that provides crucial insights for effective adaptation strategies (Maggia *et al.* eds. 2009; Nakashima *et al.* 2012).

### 4.3.3 Chemicals

Modern societies produce and inhabit the most chemical-intensive environment humans have ever experienced – today, it is estimated that there are more than 100,000 chemicals on the market of modern society (European Chemicals Agency [ECHA] 2018) – and now chemical pollution is considered a global threat (Barrows, Cathey and Petersen 2018). Common categories of chemicals include pharmaceutical and veterinary chemicals, pesticides, antibiotics, flame-retardants, plasticizers and nanomaterials (Tijani *et al.* 2016). Even the more familiar chemicals, used for generations in agriculture and industry, are now used so intensively and in such concentrations as to require responsible monitoring and evaluation programmes (Figure 4.7) (Bernhardt, Rossi and Gessner 2017).

Global chemical pollution has been raised as a problem that needs urgent action: calls for more active involvement of governments and industry and for more research are included

Figure 4.7: Chemical intensification, 1955-2015

Source: Bernhardt, Rossi and Gessner (2017).

in all relevant studies and the existence of the problem is admitted in global change assessments and clarion calls (UNEP 2012; Stehle and Schulz 2015; Bernhardt, Rossi and Gessner 2017). However, the assimilative capacities for chemical burdens are largely categorized as undetermined and then ignored, even in efforts to inspire concern about planetary environmental issues (Diamond *et al.* 2015; Steffen *et al.* 2015). The global dimension of chemical pollution manifests as these substances spread to the most remote environments on the planet, including the polar regions (Andrew 2014), high mountain peaks (Ferrario, Finizio and Villa 2017) and the deepest oceans: persistent organic pollutants were detected in fauna found at more than 10,000 metres depth in the Pacific Ocean's Mariana Trench (Jamieson *et al.* 2017). However, there are currently ongoing efforts in developed countries to carry out regular monitoring programmes to mitigate the impact of chemicals, especially pesticides, on human and environmental health (Brouwer 2018).

Some chemicals that are persistent, toxic and bioaccumulating, and may travel long distances, are listed under international conventions, such as the Stockholm Convention (persistent organic pollutants) and Minamata Convention (mercury), but scientific evidence shows that more chemicals regularly made available for commercial use display the same properties as the regulated persistent organic pollutants (Strempel *et al.* 2012). Countless new chemicals, as well as old chemicals that were not well understood, are not regulated at all even though they are suspected of causing adverse effects (Petrie, Barden and Kasprzyk-Hordern 2015; Ferrario, Finizio and Villa 2017).

Pharmaceuticals are commonly mishandled 'from cradle to grave' with over 200 different substances reported in river waters globally (Petrie, Barden and Kasprzyk-Hordern 2015). Antibiotic-resistant bacteria have evolved and spread due to mismanagement of antibacterial drugs (Marti, Variatza and Balcazar 2014; Grenni, Ancona and Caracciolo 2017). Recent research indicates that the development of antimicrobial resistance in pathogens is accelerated and achieved at lower exposure concentrations, in the presence of heavy metals and other contaminants that are commonly found in the same contaminated reservoirs (The Lancet Planetary Health 2018). The presence of such contaminants in the natural environment results from the discharge of wastewater from treatment plants that are unequipped to effectively remove these dangerous compounds (Petrie, Barden and Kasprzyk-Hordern 2015) and from mismanagement of their use for agricultural production, particularly in livestock (Hamscher and Bachour 2018).

The effects of some endocrine-disrupting chemicals are of particular concern because of potential multigenerational effects on the health of humans and wildlife (Gore *et al.* 2015). Endocrine activity or disruption has been associated with a wide variety of compounds, including some persistent organic pollutants (Kabir, Rahman and Rahman 2015) and industrial chemicals (UNEP and WHO 2013). They are present in many pesticides that are designed to interfere with the life cycles of organisms and are highly valued for those abilities (Gore *et al.* 2015). Endocrine disruption potential has also been attributed to certain chemicals present in manufactured plastics (Schug *et al.* 2016).

Products used in everyday life may contain toxic compounds that interfere with human and environmental health, spanning cosmetics, plastic containers, and household cleaners and pesticides. Addressing the issue of chemicals in products may offer new opportunities in terms of innovation through green and sustainable chemistry efforts and could represent a valuable opportunity to improve sustainable consumption and production patterns and life cycle thinking. Application of the circular economy model to chemical production and consumption could establish some measure of control from the extraction of primary materials, through the design, formulation, production, use and final disposal of the substances and products that people use (Roschangar, Sheldon and Senanayake 2015). Chemicals in everyday products, as well as endocrine disruptors and nanomaterials, have been identified as emerging policy areas under the Strategic Approach to International Chemicals Management (SAICM) (UNEP 2013b). Highly hazardous pesticides, used in agricultural practices in developing countries, are another issue addressed by SAICM: alternative approaches rely on agroecological practices to promote substitution of hazardous pesticides by pest management approaches and products that pose less risk (FAO and WHO 2016), as well as demand reduction and non-chemical alternatives.

Nanotechnology, by decreasing the particle size of materials and increasing its reactivity, may give a material some interesting properties, but these may be toxic (Schulte *et al.* 2016). There remain a number of questions about the toxicity of nanoparticles to humans and the environment, but comparison of nanomaterials of certain size and shape with asbestos indicates similar toxicological potential (Nagai and Toyokuni 2012; Allegri *et al.* 2016).

Even those substances considered under control in some regions may be distributed in developing countries with no guidance on health and safety issues and proper use. The Global Chemical Outlook (UNEP 2013b; UNEP 2013c) estimates total health-related pesticide costs – the costs of inaction – for agricultural smallholders in sub-Saharan Africa from 2015 to 2020 at US\$90 billion, assuming a continued scenario of inadequate capacity for pesticide management.

Further studies evaluating the combined effects of chemical mixtures are critical, in addition to understanding the cumulative effects of chemicals over time. Equally, more information is needed on causal linkages between exposures to certain chemicals and related health effects (The Lancet Planetary Health 2018). Promoting safer and sustainable alternatives to chemicals, especially biodegradable replacements for plastics, and sound cradle-to-cradle chemicals management is essential. Institutions and instruments are available and coordination through United Nations agencies is an objective of SAICM. The costs of inaction to global society is high if measures are not taken to detoxify the environment and to create a safe-chemical future in coming decades (UNEP 2013c).

#### 4.3.4 Waste and wastewater

The Global Waste Management Outlook (UNEP 2015) estimates the total 'urban' waste generation, including municipal solid waste, commercial and industrial waste, and construction and demolition waste, at around 7-10 billion tons per year. Waste generation rates are stabilizing in developed regions. However, Asia and Africa are expected to contribute significant amounts to global waste generation over the next century (UNEP 2015).

GEO-6 highlights key global waste management challenges consistent across the regional assessments prepared for it and prioritized in the Global Waste Management Outlook (UNEP 2015). These include food waste, marine litter, waste trafficking and crime, and the growing disparity in waste management between developed and developing countries.

Approximately one-third of the food produced for human consumption is wasted or lost annually, at a financial cost of US\$750 billion to US\$1 trillion (FAO 2013; FAO 2015; UNEP 2015). This wasted food could feed over 2 billion people, more than twice the number of undernourished people estimated globally (FAO 2013). Food losses and waste result in unnecessary greenhouse gas emissions, estimated at 3.3 gigatons of CO<sub>2</sub> equivalent in 2007, or around 9 per cent of total global GHG emissions that year (UNEP 2015). This estimate does not take into account GHG emissions as a result of land-use changes. Considering land-use changes, GHG emissions from food waste would be 25-40 per cent higher. Even without counting land-use change, if food losses and waste all occurred in one country, it would rank as the third largest country in the world in terms of CO<sub>2</sub> emissions (FAO 2013).

With increasing global demand for resources, the waste market has become a viable economic sector, estimated at US\$ 410 billion a year, from collection to recycling. In a context of increasing costs for the safe disposal of hazardous waste, weak environmental regulations and enforcement, and increasing resource scarcity, this market creates opportunities for waste trafficking and illegal activities. This is evident in large quantities of often hazardous waste being unlawfully

exported to developing countries, with the potential to cause significant, and displaced, impacts (**Figure 4.8**) (Rucevska *et al.* 2015). The illegal trafficking of end-of-life electrical and electronic equipment has become an issue of global concern (UNEP 2015; UNEP 2016b).

© Shutterstock/Fabian Ploock

**Figure 4.8: Global illegal waste traffic**

Source: Pravettoni (2015).

Developed countries have advanced their waste management systems to the point where they can consider strategies for integrating new and complex waste types; driving sustainable consumption and production; moving towards near zero waste schemes and a circular economy; and the adoption of emerging and potentially disruptive technologies on waste management. Developing countries are still grappling with basic waste management challenges, including uncontrolled dumping, open burning and inadequate access to waste services. Globally, 3 billion people lack access to controlled waste disposal facilities, according to United Nations estimates, with the potential to cause significant environmental, social and economic impacts from poor waste management (UNEP 2015). In the first seven months of 2016, an estimated 750 people died due to poor waste management at dumpsites (International Solid Waste Association [ISWA] 2016). In early 2017, some 115 people were killed in a waste landslide in Addis Ababa, Ethiopia (Gardner 2017) and 16 people were killed in the collapse of the Hulene Garbage Landfill in February 2018 in Maputo, Mozambique. A high percentage of the fatalities were women. Such dumpsites in developing countries are often home to millions of informal waste pickers (ISWA 2016; Duan, Li and Liu 2017). While developed countries chase the ideals of reduced waste, a circular economy and greater resource efficiency, developing countries must not be left behind.

Any circular economy plan incorporates wastewater in its design. This includes human sewage, industrial effluent and both agricultural and urban run-off (Mateo-Sagasta *et al.* 2013). Agriculture is the main contributor, accounting for 79 per cent of wastewater produced in arid West Asia, where it is discharged straight into the environment (**Figure 4.9**)

**Figure 4.9: West Asia non-conventional annual water resources**

Source: Abuzeid *et al.* (2014).

(AbuZeid and Elrawady 2014). It is estimated that in 2015, 68 per cent of the global population used at least some form of basic sanitation services (WHO and UNICEF 2017). However, 34 per cent of rural and only 26 per cent of urban sanitation and wastewater services actually prevent human contact with excreta along the entire sanitation chain in an effective manner (United Nations World Water Assessment Programme [WWAP] 2017). Moreover, 80 per cent of all wastewater produced globally is discharged into the environment without any treatment – wastewater contaminated with human faecal matter as well as all the pharmaceuticals and endocrine disruptors that are newly threatening human health and ecosystems (WWAP 2017). Although wastewater is a considerable resource for water and nutrients, it presents risks for public health and environmental integrity if not managed properly. Significant disease outbreaks and associated mortality (Saxena, Kaushik and Krishna Mohan 2015; Prüss-Ustün *et al.* 2016), eutrophication (Lewandowski *et al.* 2015) and soil salinization in arid lands (Qadir *et al.* 2014) are reported as main challenges associated with poorly managed wastewater.

## 4.4 Resources and materials

### 4.4.1 Resource use

Sustainable resource use requires sound management of renewable resources and aims to recycle non-renewable resources, leading to the concept of a circular economy in which a waste, the by-product of a process, becomes a raw material for another process. In a circular economy, efficient use of resources across their entire life cycle is critical: from extraction to manufacturing, through consumption and use, to recycling and reuse (Ellen MacArthur Foundation 2012; European Commission 2015).

From the 20<sup>th</sup> century, resource exploitation has grown considerably, especially of metals, such as iron and copper, and of minerals, such as sand and limestone for cement. Fossil fuel exploration and extraction, and its consumption, exemplify modern society's great advances, according to one narrative. However, fossil fuel exploitation has also created great challenges. The momentum of consumption has led to ever increasing scales of resource exploitation, leading to concerns over the cumulative and global consequences of such activities, as well as over local damage (Rockström *et al.* 2009).

Traditionally, the discovery of new and accessible deposits of non-renewable resources has kept pace with or even outpaced growing extraction, so concern over the depletion of such resources would not be considered highly important (Mudd, Weng and Jowitt 2013; Mudd and Jowitt 2014; Weng *et al.* 2015; Mudd and Jowitt 2017). However, as a measure of their quality, the grades of most mined ores are in gradual decline, meaning that the most easily and economically refined ores have already been exploited (Ruth 1995; Mudd 2010). Larger amounts of lower grade ore have to be extracted and processed to meet global demands, as can be shown by tracking exploitation of copper ore deposits (**Figure 4.10**).

When declining ore grades are combined with the larger project scales needed to extract enough ore to supply market demand, greater risks threaten the natural environment. More land is cleared, or simply removed and shipped away, as mountain-top removal illustrates. Larger volumes of mine waste accumulate, with heavy metals and reactive agents recombining into noxious compounds. Water pollution risks, especially from acid and metalliferous drainage, increase. Threats to biodiversity become more complex. Energy demand intensifies, along with associated greenhouse gas emissions (Norgate and Haque 2010). To meet global demands in 2014, the global metals

and mining industry produced around 90 billion tons of mine waste, excluding construction materials (Mudd and Jowitt 2016). This massive mining scale requires an acute focus on environmental assessment, monitoring and management for primary resource extraction (Hudson-Edwards 2016; Mudd and Jewitt 2016). Currently, much of the mine waste is stored, exposed to changing environmental and management conditions. The 2015 Samarco tailings dam failure in Brazil, among other events, demonstrated how long-term storage strategies are not solutions (Philips 2016; Roche, Thygesen and Baker 2017).

Some mined resources are widely distributed around the world, including sand, gold, copper and lead-zinc; other resources, such as nickel, rare earth elements and phosphorous, are concentrated in a small number of countries. Given the fundamental contribution of mineral resources to modern social systems, technologies and infrastructure, these materials need to be assessed for their role in modern society. This analytical approach is known as criticality – examination of the potential implications of supply disruption, resource substitution, recyclability and environmental impacts (Graedel *et al.* 2015) For example, many metals such as iron, copper, gold and lead are recyclable. Other minerals, such

**Figure 4.10: Example of ore grade decline over time for copper mining, showing world annual copper production and estimated tailings generated annually**

Source: Ruth (1995); Crowson (2012); Mudd, Weng and Jowitt (2013); Mudd and Jowitt (2016).

as phosphorous, are dispersed in soils and water bodies, ultimately washing away and being effectively lost to any further use. That kind of material dissipation raises alarms over the eventual depletion of the essential resource (Ciacci *et al.* 2015; Nassar, Graedel and Harper 2015).

In contrast, when a metal is recycled, the environmental risks are typically much lower. For instance, fabricating a product from recycled aluminium uses one-twentieth of the energy than production from primary aluminium does. For the circular economy, this means that recycling should lead to reduced environmental pressures and risks, mainly due to lower energy and raw material needs (Wernick *et al.* 1996; Wernick and Ausubel 1997; Balke *et al.* 2017). The focus of a circular economy concentrates on sound product or infrastructure design, as well as on the systems in place to monitor resource use, waste and environmental repercussions (Ghisellini, Cialani and Ulgiati 2016). Other strategies may include variations of upcycling or recycling: refuse, rethink, reduce, reuse, repair, refurbish, remanufacture and repurpose. Here, environmental and sustainability education is crucial.

An important issue arising from resource use is that the environmental and social costs are typically greatest during extraction when land is cleared, or populations displaced, while the greatest benefits accrue at the other end of the supply chain. To fully appreciate the cost-benefit ratio and the actual value of a product, it is important to consider the environmental consequences of global trade in resources, including the repercussions for local communities in areas of resource extraction. Interest is growing in tracing the origins and added values of supplied resources through sustainable supply chain management. This traceability supports action on issues such as conflict minerals, chemical and pharmaceutical waste, food contamination and illegal trade in endangered species (Mundy and Sant 2015; Paunescu, Stark and Grass 2016; Tijani *et al.* 2016; Sauer and Seuring 2017). The availability and distribution of this type of information defines a connection between supplier and consumer and encourages more sustainable resource use choices. Recent research indicates, however, that humanity has overshoot the safe operating space for certain planetary systems, specifically climate change, the rate of biodiversity loss and the biogeochemical flow of the nitrogen cycle (Rockström *et al.* 2009; Steffen *et al.* 2015). Some updated analyses would add phosphorus to that overshoot list (Carpenter and Bennett 2011; Cordell and Neset 2014).

The pressures upon our planet have therefore brought global society to a decisive crossroads: the continuation of a conventional process model to 'extract-make-use-discard' through a linear economy or the transformation into a circular economy with society focused on the entire life cycle of resource use and management. Some thinkers consider that it may already be too late (Urry 2010; Scheffer 2016). Others suggest the transition from a linear economy with wasteful resource management to a circular economy with sustainable resource management can be accomplished but requires new concepts of de-growth and a post-capitalistic economic vision (Jackson and Senker 2011; Kosoy *et al.* 2012; Krausmann *et al.* 2017).

The transition to a circular economy will provide many opportunities for technology innovation and deployment that also present many new business prospects. At heart, a circular economy will require sound policies for resource accounting

and waste management that create the demand for recycled resources and deliver a resource efficient and sustainable economy (Ghisellini, Cialani and Ulgiati 2016; Balke *et al.* 2017). Resource use is also intimately connected to energy technologies and policies, such as the materials required for various renewable energy technologies, highlighting the need to consider the links among material resources, energy and environmental outcomes (Akenji *et al.* 2016; McLellan 2017).

All 17 of the Sustainable Development Goals involve competition for natural resources, with many requiring efficient and sustainable use of resources and minimizing associated impacts – especially the metals considered critical for renewable energy and, consequently, for progress on climate change solutions (Arrobas *et al.* 2017; International Resource Panel 2017).

#### 4.4.2 Energy

By 2015, global energy consumption reached around 13.5 billion tons of oil equivalent (International Energy Agency [IEA] 2018). That is expected to increase to around 19 billion tons by 2040 (IEA 2016). Much of this increase is attributed to consumption expected in developing economies that currently depend largely on fossil-based energy sources. This makes accelerated efficiency a crucial strategy to mitigate energy-related impacts. At the same time, nearly 1.2 billion people remain without access to electricity and 2.7 billion still resort to traditional fuels for cooking and heat, facing exposure to concentrated indoor air pollution (IEA 2016). Improved access to modern energy services is not only closely connected to all Sustainable Development Goals and indicators, including food security, health and quality education, but shifting to clean and efficient forms of energy also empowers women and other marginalised groups responsible for the collection and burning of primitive solid fuels (World Energy Council 2016).

Energy demand also leads to competition for water, land and even atmospheric limits; to inequitable distribution of these and other sets of natural capital, such as mineral resources and access to sensitive ecosystems; and to processes involving different approaches that often cause disputes and conflicts at several levels and magnitudes (Rodriguez *et al.* 2013; Jägerskog *et al.* 2014; McLellan 2017).

The competition between biofuels and food re-emphasizes the need to understand the nexus of energy, food, water and land use (see Chapter 8). Popp *et al.* (2014) discuss the impact of biofuel production on food supply, environmental health and land requirements, and highlight the need for integrated policies to manage the various components of the energy, food, water and land-use nexus.

The rise in water demand, while usable water reserves decline, accentuates the need to examine water-energy linkages against the backdrop of growing energy demand. Jägerskog *et al.* (2014) discuss the energy and environmental trade-offs related to hydropower. Rodriguez *et al.* (2013) also provide an overview of water requirements for generating power, particularly in the case of thermal power plants. Copeland and Carter (2017) address the energy requirement for delivering water to end users and for the disposal of wastewater in the United States of America.

At the global scale, greenhouse gas emissions amounted to 33 gigatons of CO<sub>2</sub> equivalent in 2014 and may reach 38 gigatons in 2040, due mostly to the burning of fossil fuels (IEA 2015). Historical data demonstrate trends in decoupling through decarbonization and improved efficiency, but the current trend still indicates a global temperature increase beyond the 2°C threshold target of the Paris Agreement (**Figure 4.11**) (IEA 2015; United Nations 2015b; IEA 2016). This likely overshoot warrants bolder action.

The economics of transition to low-carbon energy sources have been greatly assisted by a dramatic reduction in the cost of renewables, especially wind and solar photovoltaic systems. Solar photovoltaic systems experienced a price decline of 23 per cent for each cumulative doubling of production over the last 35 years. In many cases these costs are now lower than those of conventional fossil fuel electricity generation technologies (International Renewable Energy Agency [IRENA] 2015). Further reductions are expected making them possibly the best economic-environmental option in practically every country in the world before 2025 (**Figure 4.12**).

Education is crucial for developing energy literacy. Seen from the perspective of the SDGs, it enables individuals to apply and evaluate measures to increase energy efficiency and sufficiency in their own lives. It also influences public policies related to energy production, supply and usage (Aguirre-Bielschowsky *et al.* 2015; UNESCO 2017a).

#### 4.4.3 Food systems

The global food system is central to sustainable development and to many of the SDGs. Across the complex interactions of activities including farming, fishing, food processing, retailing, preparing and consuming, and the multiple actors who perform them, the food system both significantly affects and is affected by environmental and social-economic dynamics (UNEP 2016c). Agriculture provides jobs for over 30 per cent of the global workforce, the majority in developing countries where 40 per cent of smallholder farmers and laborers are women (FAO 2011; FAO 2017a). Smallholder-dominated systems in developing countries produce more than half of all global food calories (Samberg *et al.* 2016) and contribute significantly to micronutrient production (Herrero *et al.* 2017). Fifty-seven million people work in fisheries and aquaculture, where women's roles are often invisible and underrecognized (Koralagama, Gupta and Pouw 2017), with many more in food manufacturing and retail (FAO 2016). A great number of these women and men live in poverty.

While the food system produces more than enough to feed the world's population adequately, it does not distribute it well. Over 800 million people are undernourished (FAO 2017a) and more than 2 billion suffer from micronutrient deficiencies (Global Panel on Agriculture and Food Systems for Nutrition 2016). However, over 2.3 billion people – about one-third of the human population – are obese or overweight (Abarca-Gómez *et al.* 2017). Diet-related diseases are globally pervasive, and many are associated with overconsumption of saturated fats and processed foods, such as type 2 diabetes, colorectal cancer and cardiovascular disease (Monteiro *et al.* 2013; Tilman and Clark 2014; UNEP 2016c). These diseases are becoming increasingly prevalent in low-income and middle-income countries, as animal protein and products high in fats and sugars become more widely available (Popkin 2006; McMichael *et al.* 2007).

The environmental footprint of the global food system is immense. It is estimated to account for 19-29 per cent of global greenhouse gas emissions (Vermeulen, Campbell and Ingram 2012). Farming is the most expansive human activity in the world, accounting for 38 per cent of global land area, and it is the principal user of fresh water, responsible for 70 per cent of withdrawals (FAO 2017a; FAO 2017b). Food production is the main driver of biodiversity loss (Kok *et al.* 2014). It is a major polluter of air, fresh water and seawater, particularly in farming systems that make heavy or poorly managed use of chemical pesticides and fertilizers (Popp, Petö and Nagy 2013; Sutton *et al.* 2013; Zhang, Zeiss and Geng 2015). Food production systems are also a leading source of soil degradation and deforestation (Amundson *et al.* 2015; Vanwalleghe *et al.* 2017; FAO 2017a). Yet the global food system is estimated to convert only 38 per cent of harvested energy and 28 per cent of harvested protein into required food consumption after accounting for losses from food waste, trophic losses from livestock and human overconsumption (Alexander *et al.* 2017).

Within the global food system's environmental footprint, the consequences of livestock raising are disproportionately large. While supplying only 18 per cent of calories and 40 per cent of protein to the world's food supply, the livestock sector accounts for about half of agriculture's greenhouse gas emissions (Gerber *et al.* 2013; FAO 2017a) and almost 80 per cent of agricultural land use – a third of all cropland is used to produce feed crops (FAO 2009). Due to the livestock sector, food production is the principal cause of habitat destruction (Machovina, Feeley and Ripple 2015) and the main disrupter of the nitrogen and phosphorous cycles that produce most of agriculture's pollution (Bouwman *et al.* 2013; Sutton *et al.* 2013). As with many resource extraction activities, the environmental burden of food production is localized, and often spatially dislocated from the consumption that drives demand. Around 20 per cent of cropland area and agricultural water use is devoted to agricultural commodities consumed in other countries (MacDonald *et al.* 2015). Similarly, overexploitation of wild fish stocks and intensive aquaculture have detrimental effects on marine and terrestrial ecosystems (see Chapter 7).

Current environmental pressures from the global food system cannot be sustained, yet to meet projected demand in 2050, with current efficiencies, world agricultural production would need to increase by 50 per cent from 2013 levels (FAO 2017a) with global crop demand forecast to increase 100-110 per cent over the same period (Tilman *et al.* 2011). Flows of nitrogen and phosphorous into the biosphere and oceans already exceed globally sustainable levels (**Figure 4.13**) (Steffen *et al.* 2015). On current trajectories, agricultural emissions are incompatible with a 2°C pathway. Action to reduce the volume and intensity of agricultural emissions, the amount of food waste and, most importantly, the share of animal products in diets will be necessary if the Paris Agreement's goal is to be achieved (Bajželj *et al.* 2014; Hedenus, Wirsénus and Johansson 2014; United Nations 2015b). On a global basis, diets with lower levels of animal products and higher levels of fruit, vegetables, pulses, whole grains and nuts are necessary to meet environmental and nutritional goals (Springmann *et al.* 2018), although particular requirements for dietary change will vary according to national context.

The food system is highly vulnerable to the pressures it is exerting on ecosystem services. Habitat loss is degrading pollinator services, with implications for crops important to human nutrition (Vanbergen 2013; Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services 2016). Land degradation decreases crop yields, and abandonment rates of agricultural land due to that degradation appear to have increased (Gibbs and Salmon 2015; United Nations Convention to Combat Desertification 2017). Rising temperatures are thought to be diminishing crop yields rather than enhancing them in certain regions, especially for wheat and maize (Asseng *et al.* 2014; Porter *et al.* 2014; Moore and Lobell 2015; Schauburger *et al.* 2017). This trend is likely to have an increasingly detrimental effect on agriculture, particularly in low-latitude developing countries, although some temperate regions may benefit from warmer temperatures and longer growing seasons in the medium term, if soil and water characteristics are right (Deryng *et al.* 2014; Porter *et al.* 2014; Zhao *et al.* 2017). Water scarcity may limit the extent to which irrigation expansion can counter climate threats to crop yields;

**Figure 4.13: The subglobal distributions and current status of the control variables for (A) biogeochemical flows of phosphorus; (B) biogeochemical flows of nitrogen**

Source: Steffen *et al.* (2015).

in fact, it may force reversion to rain-fed agriculture in a number of important crop-producing regions by the end of this century, with further consequences for crop production (Elliott *et al.* 2013). Overexploitation is already compromising groundwater in several large aquifers critical to agriculture (Gleeson *et al.* 2012).

## 4.5 Conclusions

This GEO-6 assessment offers opportunities to identify cross-cutting issues as entry points for further understanding the state of the global environment. By exploring the 12 cross-cutting issues and how they relate to the Earth system topics, GEO can demonstrate where intersections and nexus issues will need synergistic solutions with the objective of achieving true transformative change.

# Executive summary

**Concentrations of CO<sub>2</sub> and other long-lived greenhouse gases (GHGs) continue to increase**, driven mainly by people consuming fossil fuels to satisfy ever-increasing demands for energy (*well established*). {5.2.4}

Given the current concentrations of GHGs and their lifetime in the atmosphere, significant changes in climate and sea levels are unavoidable, with widespread consequences for people and the environment (*well established*). There is robust evidence that climate change and increased climate variability worsen existing poverty, exacerbate inequalities and trigger new vulnerabilities. However, even greater changes are expected in the future if action is not taken soon to halt GHG emissions. {5.3.4}

**Climate change impacts include increased frequency and magnitude of heatwaves and storms** (*established but incomplete*); changes in the distribution of disease vectors, exacerbation of air pollution episodes, and decreases in water supply and impacts on crop yields and food prices. {5.3.4}

Efforts to decrease emissions of short-lived climate pollutants (SLCP), specifically black carbon (BC), methane (CH<sub>4</sub>), tropospheric ozone (O<sub>3</sub>) and hydrofluorocarbons (HFCs), are a critical component of an integrated climate change mitigation and air quality management programme (*well established*). Along with rapid mitigation of long-lived GHG emissions, decreases in SLCP emissions achieve the objectives of the United Nations Framework Convention on Climate Change (UNFCCC). {5.2.4}

Air pollution is the most important environmental contributor to the global burden of disease, leading to an estimated 6 million to 7 million premature deaths annually and large economic losses (*established but incomplete*). Of those deaths, 2.6 million to 3.8 million deaths have been attributed to burning wood, coal, crop residue, dung and kerosene for cooking, heating and lighting. Another 3.2 million to 3.5 million deaths have been attributed to other sources of ambient air pollution. The monetary value of the global welfare losses has been estimated at US\$5.1 trillion (or 6.6 per cent of global world product). {5.3.1}

People who are elderly, very young, sick and poor are more susceptible to air pollution, which can exacerbate pre-existing illnesses or conditions (*well established*). Exposures are highest for people living in urban areas in low- and middle-income countries and for the approximately 3 billion people who depend on burning solid fuels or kerosene to meet household energy needs. {5.3.1}

Globally, decreasing emission trends in some sectors and regions have been offset by increasing emission trends in rapidly developing and emerging economies and areas of rapid urbanization (*well established*). {5.2}

East and South Asia have the highest total number of deaths attributable to air pollution, due to large populations and cities with high levels of pollution (*well established*). These regions also bear the largest health burden caused by the production of goods consumed in other regions of the world, primarily Western Europe and North America. {5.3.1}

As controls have been placed on power plants, large industrial facilities and vehicles, the relative contributions of other sources have grown in importance (*well established*). Sources of pollution that are increasingly relevant to achieving air quality objectives include agriculture, domestic fuel burning, construction and other portable equipment, artisanal manufacturing and fires. The relative contributions of these sources to air quality problems differs from region to region, such that priorities for air pollution control may vary in different locations. {5.2.1}

**Emissions of ozone-depleting substances (ODSs) have decreased dramatically as a result of the Montreal Protocol** (*well established*). New studies provide robust evidence that stratospheric ozone over Antarctica has started to recover. Although stratospheric ozone concentrations in other regions have increased since 2000, the expected increase in total atmospheric column ozone and decrease in ultraviolet (UV) radiation reaching the Earth's surface have not been observed outside Antarctica due to natural variability, increases in GHGs, and changes in attenuation of the UV radiation by tropospheric ozone, clouds and aerosols. {5.2.3}

**International agreements have been successful in addressing specific chemicals, but new chemical risks are emerging** (*established but incomplete*). Environmental concentrations of persistent organic pollutants (POPs) have been reduced in Europe, North America, Asia and the Pacific, and the Arctic. {5.2.2}

Rapid development and urbanization combined with insufficient environmental governance in many regions suggest that climate change and air pollution are likely to worsen before they improve without additional policy interventions (*well established*). However, future policy efforts can build upon renewed attention to these issues in international forums and several decades of experience with various governance strategies in different countries. {5.4}

## 5.1 Introduction

Emissions generated by human activity have changed the composition of the Earth's atmosphere, with consequences for the health of people and the planet. The impacts of human activity on the atmosphere are often framed in terms of four separate challenges: air pollution; climate change; stratospheric ozone depletion; and persistent, bioaccumulative, toxic substances (PBT) (Abelkop, Graham and Royer 2017). The causes of these four challenges, their effects on atmospheric composition and meteorological processes, and their impacts on humans and ecosystems are closely intertwined (see Figure 5.1). Solutions to these challenges are also interrelated, as changes in lifestyle, technology and policy alter emissions of multiple pollutants simultaneously with a variety of interrelated implications. This chapter describes these four challenges together following the Drivers, Pressures, State, Impact, Response (DPSIR) framework (see Section 1.6).

Since the fifth Global Environment Outlook (GEO-5) was published in 2012, a number of developments have focused international attention on changing atmospheric composition. Estimates of the global burden of disease contributed by air pollution have doubled (comparing assessments published in 2004, 2012 and 2017) primarily due to new exposure estimates informed by satellite-borne instruments (Lim *et al.* 2012; Cohen *et al.* 2017). The United Nations Environment Assembly of the United Nations Environment Programme (UNEA) (2014; 2017) and World Health Assembly of the World Health Organization (WHO) (2015) have responded with resolutions to encourage national-level actions to address air pollution. Concentrations of major GHGs are still growing strongly (World Meteorological Organization [WMO] 2017a) and indicators of climate change

Table 5.1: Some atmospheric chemical components

|                   |                                                                        |
|-------------------|------------------------------------------------------------------------|
| BC                | black carbon                                                           |
| CFCs              | chlorofluorocarbons                                                    |
| CH <sub>4</sub>   | methane                                                                |
| CO                | carbon monoxide                                                        |
| CO <sub>2</sub>   | carbon dioxide                                                         |
| GHGs              | greenhouse gases                                                       |
| HCFCs             | hydrochlorofluorocarbons                                               |
| HFCs              | hydrofluorocarbons                                                     |
| Hg                | mercury                                                                |
| N <sub>2</sub> O  | nitrous oxide                                                          |
| NH <sub>3</sub>   | ammonia                                                                |
| NMVOC             | non-methane volatile organic compounds                                 |
| NO                | nitrogen oxide                                                         |
| NO <sub>2</sub>   | nitrogen dioxide                                                       |
| NO <sub>x</sub>   | nitrogen oxides                                                        |
| O <sub>3</sub>    | ozone, tropospheric and stratospheric                                  |
| OC                | organic carbon                                                         |
| ODS               | ozone-depleting substances                                             |
| PAHs              | polycyclic aromatic hydrocarbons                                       |
| Pb                | lead                                                                   |
| PBDE              | polybrominated diphenyl ethers                                         |
| PBTs              | persistent, bioaccumulative, toxic chemicals (includes POPs, metals)   |
| PCB               | polychlorinated biphenyl                                               |
| PFAS              | per- and polyfluoroalkyl substances                                    |
| PM                | particulate matter                                                     |
| PM <sub>10</sub>  | PM less than 10 µm in diameter                                         |
| PM <sub>2.5</sub> | PM less than 2.5 µm in diameter                                        |
| POPs              | persistent organic pollutants (as defined by international agreements) |
| SO <sub>2</sub>   | sulphur dioxide                                                        |

Figure 5.1: Primary linkages between pressures, state and impacts of atmospheric change

This figure is intended as a road map for the reader, showing the relationships between the main topics and pollutants discussed in this chapter. Chemical symbols and abbreviations are defined in Table 5.1.

have continued to accumulate. Targets in the Kyoto Protocol of the United Nations Framework Convention on Climate Change (UNFCCC) expired but were replaced by new ones under the Doha Amendment and new commitments under the Paris Agreement (UNFCCC 2016). Complementing the work of the UNFCCC, new efforts have targeted reductions of short-lived climate pollutants (SLCPs) from specific sectors with benefits for climate change mitigation and human health (Climate and Clean Air Coalition [CCAC] 2015). As stratospheric ozone ( $O_3$ ) has continued its recovery, the Kigali Amendment to the Montreal Protocol (United Nations 2016a) has harnessed this successful international agreement to help mitigate the climate impacts of hydrofluorocarbons (HFCs), originally introduced as substitutes for ozone-depleting substances (ODS). Emissions of mercury (Hg) have declined in some regions and increased in others. Emissions of some banned persistent organic pollutants (POPs) have declined due to the implementation of international agreements. However, atmospheric burdens of other POPs and PBTs remain at levels of concern, and new chemical risks have been identified (United Nations Environment Programme [UNEP] 2017a).

Efforts to achieve each of the Sustainable Development Goals (SDGs) are linked directly or indirectly to mitigating air emissions and changes to atmospheric composition, as shown in **Figure 5.2**.

In the GEO-6 regional assessments, air pollution, climate change and energy development, as well as the intersection of these three issues, were identified as top priorities in every region. Growing cities, energy, and transportation demand were consistently identified as issues of concern. Indoor air pollution and access to clean household energy were priorities in Africa and Asia. Other regional priorities highlight differences in the

institutional capacities of governments in different regions: improving observational networks (Africa, Latin America and the Caribbean, West Asia), strengthening governance (Asia, Latin America and the Caribbean), and understanding costs and benefits of mitigation measures (Asia). The following sections build upon the GEO-6 regional assessments to explore the state of these challenges from a global perspective.

## 5.2 Pressures: emissions

People alter the atmosphere primarily by generating emissions. Trends in human-caused emissions are driven by changes in population, urbanization, economic activity, technology and climate ('the drivers'), as well as by behavioural choices, including lifestyle, and conflict. In turn, these drivers are influenced by policies ('responses'). Natural emission sources, including emissions from vegetation, soils, wildfires, and windblown sand and dust, also contribute to emissions, but can be affected by people (e.g. through land-use change).

Although an increasing amount of emissions information in some GEO regions is publicly available, there is no global reporting programme applicable to all sources and pollutants and no comprehensive emissions data repository. The Aarhus Convention and its Protocol on Pollutant Release and Transfer Registers (PRTR) aspires to establish a global network, building on the work of the United Nations Economic Commission for Europe (UNECE) and the Organisation for Economic Co-operation and Development (OECD) (see <http://prtr.net>). Currently, compiling a consistent global emissions inventory requires research effort. This assessment uses the latest anthropogenic emissions data developed using the Community Emissions Data System (CEDS), an open source, global emissions inventory data system that was developed

**Figure 5.2: Linkages between changes in atmospheric composition and achievement of the Sustainable Development Goals**

Direct linkages are shown with bold arrows, indirect linkages with light arrows.

© Shutterstock WithayaP

to provide consistent long-term emission trends for use in global atmospheric modelling efforts, such as those supporting the preparation of Intergovernmental Panel on Climate Change (IPCC) 6<sup>th</sup> Assessment Report (Hoesly *et al.* 2018). Open biomass burning emissions, whether anthropogenic or natural, are drawn from a separate inventory created for global modelling efforts by merging information from satellite-based estimates, sedimentary charcoal records, historical visibility records and multiple fire models (van Marle *et al.* 2017). Together, these data sets provide an up-to-date and consistent basis to examine trends for most air pollutants and greenhouse gases (GHGs) (see Figure 5.3).

Globally, anthropogenic carbon dioxide (CO<sub>2</sub>) emissions increased by more than 40 per cent over the period 1990-2014, driven by large increases in Asia and counteracted by small declines in North America and Europe. Sulphur dioxide (SO<sub>2</sub>) emissions are the only ones to have declined globally during this period, with increases of more than 50 per cent in Asia offset by a more than 75 per cent decrease in North America and Europe. In recent years, emissions of SO<sub>2</sub> and nitrogen

oxides (NO<sub>x</sub>) have begun to decline in East Asia. The inclusion of wild and agricultural fires significantly increases the inter-annual variability of emissions of non-methane volatile organic compounds (NMVOC), carbon monoxide (CO), black carbon (BC) and organic carbon (OC).

The emissions data presented here are best estimates with different degrees of uncertainty depending on pollutant, sector, region and time period. Hoesly *et al.* (2018) found that CEDS estimates are slightly higher than previous global inventories (e.g. Lamarque *et al.* 2010; European Commission 2016). In general, estimates of CO<sub>2</sub> and SO<sub>2</sub> emissions have uncertainties on the order of ±10 per cent for a 5-95 per cent confidence interval, whereas BC and OC emissions have uncertainties on the order of a factor of two. Uncertainties for CO, NO<sub>x</sub>, NMVOC and ammonia (NH<sub>3</sub>) emissions lie in between these two endpoints (Hoesly *et al.* 2018). Uncertainty also varies by sector: emissions from large electricity generation plants are well characterized, whereas emissions generated by military conflicts are not well understood or commonly included in inventories.

Figure 5.3: Annual emission trends from 1990 to 2014 in kilotons by pollutant, region and sector

Source: Hoesly *et al.* (2018).

Figure 5.3 (continued): Annual emission trends from 1990 to 2014 in kilotons by pollutant, region and sector

Source: Hoesly et al. (2018).

**Figure 5.3 (continued): Annual emission trends from 1990 to 2014 in kilotons by pollutant, region and sector**

Source: Hoesly *et al.* (2018).

There are considerable gaps in available emissions data for POPs, which include pesticides, industrial chemicals and products of incomplete combustion or chemical reactions. Available data in Europe, America and Central Asia indicate that emissions decreased significantly between 1990 and 2012 for the most studied POPs, due to regulations, including the Stockholm Convention (UNEP 2014a; UNEP 2014b; UNEP 2015a; UNEP 2015b). Nevertheless, alongside the growing number of listed POPs and candidate substances, unregulated POPs emissions may be increasing. Many commercial products contain unknown quantities and types of unregulated POPs, often with unknown effects (see also Section 4.3.3).

The UNEP Global Mercury Assessment estimated that anthropogenic Hg emissions to air were 2,220 (2,000-2,820) (metric) tons/year for 2015 (UNEP 2013a). Globally, artisanal and small-scale gold mining (ASGM) was responsible for about 38 per cent of total anthropogenic Hg emissions to air in 2015, followed by coal combustion (about 21 per cent), non-ferrous metal production (about 15 per cent) and cement production (about 11 per cent). Asia is the main source region, contributing about 49 per cent of 2015 global anthropogenic Hg emissions, followed by South America (18 per cent) and sub-Saharan Africa (16 per cent). Current anthropogenic sources contribute about 30 per cent of annual Hg emissions to air, while natural geological sources contribute about 10 per cent. The remaining 60 per cent comes from 're-emissions' of previously released Hg from soils and oceans, mostly from anthropogenic sources (UNEP 2013a).

Globally, both the production and consumption of ODS, and thus ODS emissions, declined by more than 99 per cent between 1990 and 2016 (UNEP 2017b). Chlorofluorocarbons (CFCs) and halons, the most potent ozone depleters, have been replaced by shorter-lived hydrochlorofluorocarbons (HCFCs) and hydrofluorocarbons (HFCs), although recent measurements suggest that new emissions of trichlorofluoromethane (CFC-11) may be occurring (Montzka *et al.* 2018). The less-depleting HCFCs are now being phased out in favour of chemicals that do not contribute to ozone depletion. Concerns about the potential future contribution of HFCs to climate change led to the 2016 Kigali Amendment to the Montreal Protocol, which will limit future HFC emissions.

### 5.2.1 Electricity and fuel production

The electricity and fuel production sector (labelled 'energy' in **Figure 5.3**) is the largest anthropogenic emitting sector of CO<sub>2</sub>, methane (CH<sub>4</sub>), SO<sub>2</sub> and NMVOC, and the main emitting sector of other air pollutants. Within the sector, electricity generation contributed around 70 per cent of CO<sub>2</sub>, 71 per cent of SO<sub>2</sub> and 72 per cent of NO<sub>x</sub> in 2014 (Hoesly *et al.* 2018).

**Figure 5.4: Global fuel shares of electricity generation in 2015<sup>1</sup>**

Notes: <sup>1</sup> Excludes electricity generation from pumped storage. <sup>2</sup> Includes geothermal, solar, wind, heat, etc. <sup>3</sup> Peat and oil shale are aggregated with coal.

Source: IEA (2017).

Despite increases in renewable energy capacity, fossil fuels still dominate the global power system (see **Figure 5.5**). Three-quarters of the sector's SO<sub>2</sub> emissions, 70 per cent of its NO<sub>x</sub> emissions and over 90 per cent of those of primary particulate matter less than 2.5 µm in diameter (PM<sub>2.5</sub>) are from coal-fired plants. Coal combustion is also the second most important anthropogenic source of global Hg emissions (International Energy Agency [IEA] 2016a). In 2015, gas-fired generation

emitted close to 20 per cent of NO<sub>x</sub> from power generation, but barely any SO<sub>2</sub> or primary PM<sub>2.5</sub> (IEA 2016a).

From 1990 to 2015, global petroleum fuel production saw slow but sustained growth (see **Figure 5.5**). CH<sub>4</sub> and NMVOC emissions from fuel production showed a corresponding increase (**Figure 5.3**). However, for electricity generation, production doubled between 1990 and 2015 (**Figure 5.6**),

**Figure 5.5: World petroleum refinery output by-product (million tons)**

Source: IEA (2017).

**Figure 5.6: World electricity generation by fuel (terawatt hours)<sup>1</sup>**

Notes: <sup>1</sup> Excludes electricity generation from pumped storage. <sup>2</sup> Other = geothermal, solar, wind, tide, wave, ocean, biofuels, heat, etc.

Source: IEA (2017).

but emissions of air pollutants did not increase at the same rate. Most importantly, SO<sub>2</sub> emissions from electricity generation declined after 2006 (see **Figure 5.3**). The main reasons for this decoupling include:

- 1 improvement of energy efficiency;
- 2 tighter emission standards for power plants and progress of end-of-pipe control technologies;
- 3 development of natural gas, renewable and nuclear power (Renewable Energy Policy Network for the 21st Century [REN21] 2016).

However, despite existing policies and the announced aims, targets and intentions, electricity demand is expected to increase by two-thirds by 2040 (IEA 2016b). Both end-of-pipe pollution control technologies and coal with low sulphur content may be used to achieve lower air pollutant emissions.

## 5.2.2 Transportation

In all regions of the world, the transportation of people and goods are significant sources of emissions of air pollutants, GHGs, ODS (from automobile air-conditioning units) and PBTs (including lead [Pb] and other metals). Road transport, including petrol- (gasoline-) and diesel-fuelled passenger cars and heavy-duty trucks, account for a dominant fraction of NO<sub>x</sub> emissions, and a significant fraction of CO<sub>2</sub>, CO, NMVOC and BC emissions (see **Figure 5.3**; Hoesly *et al.* 2018). Road traffic also contributes to emissions of primary PM from tyre and brake wear and entrained road dust (not included in **Figure 5.3**). Because cars and trucks operate and emit pollutants near where people live and work, they have a larger impact on air pollution exposures and associated health impacts than is proportional to their fraction of total emissions.

Total road transport activity is higher in North America and Europe than in other regions and is therefore responsible for greater CO<sub>2</sub> emissions, but those emissions have held steady for the last decade, with improvements in fuel efficiency keeping pace with increasing transport demand (Hoesly *et al.* 2018). The emissions of other transportation-related pollutants in North America and Europe have declined due to the introduction of vehicle emissions and fuel standards (see Section 12.2).

In developing countries, road transport emissions continue to rise as vehicle use is increasing faster than technological improvements, despite the introduction of emissions and fuel standards, which lag behind those in North America and Europe. Implementation of cleaner technologies is slowed by the trade in used vehicles from richer countries (UNECE and UNEP 2017). However, continued progress towards decreasing the sulphur content of fuel will enable the use of advanced emission control systems in all countries.

As emission standards are more widely applied to road vehicles, the relative fraction of emissions from non-road vehicles, such as heavy-duty construction equipment, is becoming increasingly important. Often running on diesel fuel, and with long lifetimes, such vehicles can be good candidates for retrofit control technologies or alternative fuels.

Maritime shipping is used to transport 80 per cent of global trade measured by volume (International Transport Forum

2017) and grew by more than 300 per cent between 1990 and 2015 when measured by ton-miles (United Nations Conference on Trade and Development [UNCTAD] 1997; UNCTAD 2017). Typically burning the heaviest petroleum products, ships are a significant source of SO<sub>2</sub> and CO<sub>2</sub> emissions globally and a source of SO<sub>2</sub>, NO<sub>x</sub> and BC emissions in coastal regions and port cities. Emission Control Areas have been established under international law (e.g. covering the North and Baltic seas and North American coastal waters) and national laws (e.g. covering Chinese ports and inland waters). The International Maritime Organization has announced new emission and fuel standards that are expected to dramatically decrease shipping emissions starting in 2020.

Aviation is a small but growing contributor to global emissions, accounting for less than about 2 per cent of global anthropogenic CO<sub>2</sub> emissions from fuel combustion (IEA 2017). Between 2000 and 2016, global air passenger travel increased 235 per cent (measured in passenger-km) and airfreight increased 174 per cent (measured in tons-km) (International Civil Aviation Organization [ICAO] 2016a). Aircraft emit pollutants directly into the upper atmosphere where their impact on ozone formation and climate forcing is larger than if emitted near the surface. The contribution of aviation CO<sub>2</sub> to radiative forcing is well quantified, but planes also emit water vapour, other gases and aerosols at high altitudes that trigger cloud formation and modify natural clouds and alter ozone and methane concentrations in the upper troposphere and lower stratosphere. The effects of these changes on climate forcing are not well quantified (Brasseur *et al.* 2016; Fahey *et al.* 2016). In 2016, the International Civil Aviation Organization (ICAO) adopted the Carbon Offsetting and Reduction Scheme for International Aviation (CORSIA), with a goal of capping the net CO<sub>2</sub> emissions from international aviation at 2020 levels (ICAO 2016b).

## 5.2.3 Industrial

Industry includes both manufacturing and mining sectors. The industrial sector emits air pollutants, GHGs, ODSs and PBTs, providing opportunities for multi-pollutant controls. Emissions and emission controls are often industry and process specific, or even regionally specific for some industries.

Nearly two-thirds of historic CO<sub>2</sub> and CH<sub>4</sub> emissions can be attributed to 90 investor- or government-owned businesses involved in the production of fossil fuels and cement (Heede 2014). Global emissions from industry increased for all pollutants between 1990 and 2014, except for SO<sub>2</sub> (**Figure 5.3**), due to decreases in Europe's and North America's emissions being smaller than increases in other continents. Global SO<sub>2</sub> industrial emissions declined by 26 per cent from 1990 to 1999, due to the decrease in European and North American emissions, and increased after 1999, due to a considerable increase in China's (up to 2012 and reduced thereafter; Zheng *et al.* 2018) and other Asian countries' emissions (Hoesly *et al.* 2018).

The creation of many new industrial products, nanomaterials and chemicals poses a considerable challenge in terms of regulation and control. Their emissions are often neither regulated nor quantified, leading to unknown effects on the environment and health.

Technological innovation, technology transfer and tighter emission regulations to improve energy efficiency in

manufacturing and mining sectors are key to reducing emissions. Examples include cleaner brick kiln technology, piloted in Asia and Latin America (Maithel *et al.* 2012; Center for Human Rights and Environment 2015); cleaner technologies and approaches to reduce or eliminate mercury use in ASGM piloted in several countries (United States Environmental Protection Agency [US EPA] 2018a); and Perform-Achieve-Trade schemes for energy intensive industry in India (Kumar and Agarwala 2013; Bhandari and Shrimali 2018).

#### 5.2.4 Residential and commercial

Around 3.1 billion people, about 43 per cent of the global population in 2014, depend on burning fuels such as wood, crop residue, dung, coal and kerosene to cook their food and heat and light their homes (World Health Organization [WHO] 2016a). These fuels are the dominant source of BC and OC emissions globally and a major source of primary PM, polycyclic aromatic hydrocarbons (PAHs), CO and CO<sub>2</sub> emissions (Hoesly *et al.* 2018). Globally, exposure to residential smoke is one of the largest environmental health risk factors (Cohen *et al.* 2017). Lack of access to clean household energy is most severe in low- and middle-income countries, but the use of polluting fuels takes place in high-income countries and in urban as well as rural areas. Women and children are the most exposed to household air pollution, and also bear the greatest burden of gathering or procuring the fuels (WHO 2016b). Improving access to cleaner stoves and fuels (including wood pellets, liquid petroleum gas, natural gas, and sources of electricity) has been identified as a global priority, and although progress is being made, many challenges remain (Global Alliance for Clean Cookstoves 2014; WHO 2016a) (see Section 12.2.3).

The energy demands of the built environment (primarily the construction, heating, cooling, and lighting of residential and commercial buildings) account for a large fraction of GHG emissions in countries with developed economies and some cities in developing economies. Improving the energy efficiency of buildings and cities is necessary to meet global goals for GHG mitigation and to achieve co-benefits for air quality. These improvements require policy approaches such as building standards, labelling and rating systems, land-use planning, tax incentives, financing, voluntary commitments, awareness and education.

#### 5.2.5 Waste management

While most developed countries have shifted towards cleaner and more efficient technologies for waste management, developing countries are still grappling with basic challenges in this area. Open dumping and burning of solid waste remain predominant in low-income countries and continues to be practised in many cities in lower-middle and upper-middle income countries. An estimated 2 billion people worldwide lack access to solid waste collection services, while 3 billion people lack access to adequate waste disposal facilities (UNEP and International Solid Waste Association 2015). Approximately 64 million people are directly affected by uncontrolled dumping and open burning at the world's 50 largest dumpsites, 42 of which are within 2 km of settlements (Waste Atlas Partnership 2014).

Open waste burning emits CO<sub>2</sub>, CH<sub>4</sub>, NMVOC and PM, and is a major source of POPs, including dioxins and furans, in many developing countries (UNEP 2014a; UNEP 2014b; UNEP 2015a; UNEP 2015b). In developed countries, the waste sector is also an important source of CH<sub>4</sub>, metals and POPs. The illicit export of discarded electrical and electronic equipment (e-waste) from industrialized to developing countries (Rucevska *et al.* 2015) leads to significant emissions of POPs as well as other semivolatile organic contaminants (e.g. other halogenated flame retardants) in the informal e-waste receiving and processing areas (Breivik *et al.* 2016).

#### 5.2.6 Agricultural and forestry

A broad array of agricultural and livestock farming practices alter the nitrogen cycle and GHG emissions, and increase pollution by fertilizers and pesticides, promoting biodiversity loss and soil degradation (DeLonge, Miles and Carlisle 2016). Agriculture, forestry and other land uses contribute 25 per cent to global GHG emissions (Seto *et al.* 2014). In developed countries, agriculture forms about 10 per cent of national GHG inventories (European Environment Agency 2017; US EPA 2017), while in developing countries the contribution is much higher.

Meat and dairy production, distribution and consumption have large environmental impacts on scales ranging from local to global (Leip *et al.* 2015). Industrial meat production and livestock operations are significant sources of GHGs, NH<sub>3</sub>, dust and bioaerosols (Cole and McCoskey 2013). GHG emissions from livestock farming increased by 51 per cent globally between 1961 and 2010, mostly due to a 117 per cent increase in developing countries, moderated by a 23 per cent decrease in the developed countries (Caro *et al.* 2014; Pagano *et al.* 2017). Livestock production is responsible for 9 per cent of total GHG emissions (Caro *et al.* 2014). The largest source of these emissions (74 per cent) are dairy and beef cattle. N<sub>2</sub>O and CH<sub>4</sub> emissions, which emanate from manure left on pasture, manure management and fermentation, increased by 57 per cent globally in the same period. However, rotational livestock grazing and other pasture management techniques are available to decrease the production of GHGs by the very same cattle, and at the same time preserve biodiversity (Nordborg and Røos 2016).

Along with livestock farming, fertilizer use results in significant emissions of NH<sub>3</sub>, accounting for about 75 per cent of anthropogenic and about 60 per cent of total NH<sub>3</sub> emissions globally (Ciais *et al.* 2013) and contributing to regional PM formation and detrimental effects on terrestrial, freshwater and marine ecosystems (Galloway *et al.* 2003).

Irrigation and fertilization practices for crops in general, as well as pasture management, can alter soil respiration rates, changing the amount of CO<sub>2</sub> emitted by soils to the atmosphere (UNEP 2017c). Pesticides used in agricultural applications are a major source of unregulated POPs into the environment and food chain, with various detrimental effects on health (see Section 4.3.4).

Biomass burning – including natural wildfires, prescribed burning of crop and forest residues, and prescribed burning of forests and savannah for land clearing – contributes significantly to air pollution by emitting CO, OC, BC, NO<sub>x</sub> and NH<sub>3</sub>, as well as GHGs, CO<sub>2</sub> and CH<sub>4</sub>. Dominant types of biomass burned are savannah in Africa; boreal forest in the former Soviet Union, savannah and tropical forest in Latin America; and savannah, peat and tropical forest in eastern Asia. Biomass burning in South-East Asia, the drought triggered by the 2015-2016 El-Niño, coupled with anthropogenically induced deforestation over peat swamps and effects of previous widespread fires, have all led to severe regional air pollution events (Wooster, Perry and Zoumas 2012; Kopplitz *et al.* 2016; Parker *et al.* 2016) (see Section 12.2.5).

### 5.2.7 Natural emissions and land-use change

Natural sources also contribute to emissions, but people have a strong influence on these in some regions through land-use change, especially cropland expansion (Pacífico *et al.* 2012; Ciais *et al.* 2013). Wind-blown dust from natural landscapes and unprotected cropland in arid and semi-arid regions is the largest source of atmospheric PM and the dominant fraction of coarse PM in many regions, such as northern Africa and the Middle East (Ginoux *et al.* 2012; Albani *et al.* 2014). Sustainable land and water management practices can decrease sand and dust storms, while contributing to reduced desertification, preserving biodiversity and mitigating climate change. Regional and national action plans, including those developed under the United Nations Convention to Combat Desertification (UNCCD), have the potential to address the underlying causes of sand and dust storms (UNEP, WMO and UNCCD 2016).

Globally, terrestrial vegetation is the dominant source of atmospheric NMVOCs, outweighing anthropogenic sources by a factor of ten (Guenther *et al.* 2012; Sindelarova *et al.* 2014). Biogenic NMVOCs tend to be highly reactive and can contribute significantly to O<sub>3</sub> and PM formation even in urban areas (Chameides *et al.* 1988). Soil microbial processes are an important part of the nitrogen cycle and can be a significant source of NO<sub>x</sub> emissions outside urban areas and the dominant source of nitrous oxide (N<sub>2</sub>O), a potent GHG, on a global basis (Ciais *et al.* 2013). Soil NO<sub>x</sub> emissions are highest in croplands due to increased soil nitrogen content from fertilizer application (Vinken *et al.* 2014). Deforestation associated with expansion of croplands and pasturelands is estimated to have reduced global annual biogenic NMVOC emissions by 10-35 per cent and increased soil NO<sub>x</sub> emissions by about 50 per cent since the 1850s, except in parts of the eastern United States and Western Europe where reforestation has taken place (Unger 2014; Heald and Geddes 2016). Bouwman *et al.* (2013) estimated that agricultural soil N<sub>2</sub>O emissions increased by a factor of three during the 20th century.

Soil respiration is a major source of CO<sub>2</sub> to the atmosphere at a global scale (Hashimoto *et al.* 2015) that in recent decades has increased its contribution (Bond-Lamberty *et al.* 2018).

## 5.3 State: atmospheric composition and climate

For meteorology and climate variables, a well-developed global observation system with spatial coverage adequate to monitor regional patterns is coordinated by WMO. For atmospheric composition, however, the amount of information available varies significantly by pollutant and region. Countries in North America, Europe and East Asia, have well-developed in-situ ground-based monitoring networks for ground-level O<sub>3</sub> and PM, as well as SO<sub>2</sub>, CO and, in some areas, NO and NO<sub>2</sub>. For other pollutants, observations tend to be relatively sparse. There is a need for a global catalogue of monitoring station metadata, currently being pursued through expansion of the WMO Global Atmosphere Watch Station Information System (GAWSiS, <https://gawsis.meteoswiss.ch>) and Observing Systems Capability Analysis and Review (OSCAR, <https://oscar.wmo.int>) tool. For many regions of the world, however, ground-based networks do not have sufficient density and coverage to characterize spatially representative trends. Observations from satellites, aircraft and other platforms, as well as atmospheric chemistry and transport models, are needed to complement traditional networks.

Existing polar-orbiting satellite instruments provide global observations of a number of important air pollutants (including PM, O<sub>3</sub>, CO, SO<sub>2</sub>, NO<sub>2</sub>, NH<sub>3</sub>, formaldehyde and CH<sub>4</sub>) albeit with relatively coarse temporal, spatial and vertical resolution (Duncan *et al.* 2014; Duncan *et al.* 2016). In some parts of the world, however, monthly average total column observations from satellites provide the only information available. Current efforts to improve understanding of the relationship between space-based and ground-based observations should help to fill data gaps in areas with sparse monitoring (e.g. Snider *et al.* 2015).

Space agencies in the Republic of Korea, the United States of America and Europe are working to deploy a constellation of geostationary satellites over East Asia, North America, Europe, North Africa and the Mediterranean to measure O<sub>3</sub>, PM and their precursors. In geostationary orbit, these instruments will have much finer temporal and spatial resolution than current polar-orbiting satellites, providing a wealth of information about air pollution over these regions in near real-time (Committee on Earth Observing Satellites 2011).

At the other end of the spectrum of cost and complexity, inexpensive electronic sensors for measuring different pollutants are being developed, marketed to governments, businesses and even individuals, and deployed in a variety of mobile and stationary settings (e.g. Apte *et al.* 2017). The quality of information varies significantly and is currently low, but efforts are in place to better understand the performance of different sensors, and to develop standardized tests and guidance on how to deploy and use the observations gathered (UNEP 2016; Lewis *et al.* 2017; US EPA 2018b).

Increasingly, air quality information from ground-based networks as well as air quality forecasts are being made available publicly. The United States of America pioneered such systems with AirNow.gov starting in 1998, and similar information is now available in countries and cities worldwide, as well as through open source platforms (e.g. OpenAQ.org) (see Section 12.2.4).

### 5.3.1 Air pollution: urban to global scales

From a global public health perspective, the two most important air pollutants are PM and its components and ground-level  $O_3$ . Ambient PM may be emitted directly as a fine particle (e.g. BC, OC and soil dust) or formed in the atmosphere from emissions of gaseous precursors (e.g.  $SO_2$ ,  $NO_x$ ,  $NH_3$  and NMVOC). Ground-level  $O_3$  is not directly emitted but is formed in the atmosphere from reactions of  $NO_x$ , NMVOC,  $CH_4$  and CO (Seinfeld and Pandis 2016). Globally, the highest annual average concentrations of  $PM_{2.5}$  are seen in areas affected by windblown sand and dust (e.g. northern Africa and west Asia), fires (e.g. Central Africa and Latin America) and anthropogenic pollution (e.g. South and East Asia) (Cohen *et al.* 2017; Shaddick *et al.* 2018) (see **Figure 5.7**). From 1998 to 2012, satellite observations suggest that  $PM_{2.5}$  decreased significantly over eastern North America, and increased over west Asia, South Asia and East Asia (Boys *et al.* 2014). Ground-based measurements suggest that the trends over North America, South Asia and East Asia are associated with changes in anthropogenic pollution, but the changes over west Asia are due to changes in windblown sand and dust (Boys *et al.* 2014).

Ground-level  $O_3$  is highest in the northern mid latitudes and tropics, and peaks in the warm season. North America, the Mediterranean, South Asia and East Asia are hotspots for  $O_3$  pollution (see **Figure 5.8**). However, high population weighted  $O_3$  concentrations are also estimated in Central Africa, west Asia and South-East Asia (Health Effects Institute 2017).

Satellite observations have identified rapid changes in the ground-level concentrations of  $SO_2$  and  $NO_2$  over the last 10-15 years, with declining trends in Europe and North America, and increasing trends in some regions in East Asia, South Asia, Africa and South America (Schneider, Lahoz and van der A 2015; Geddes *et al.* 2016; Krotkov *et al.* 2016).

**Figure 5.7: Annual average  $PM_{2.5}$  concentrations in 2016 compared with the WHO Air Quality guideline and interim targets**

Source: Shaddick *et al.* (2018).

**Figure 5.8: Seasonal average population-weighted  $O_3$  concentration in 2016 for season with maximum ozone levels by country**

Source: HEI (2018).

Urban areas, which are home to over half of the world's population, have higher overall levels of air pollution. A review of published  $\text{PM}_{2.5}$  observations for 71 megacities (over 5 million people) for 2013 found that, of the 45 megacities with available observations, only 4 attained the WHO guideline for annual average concentrations (Cheng *et al.* 2016) (**Figure 5.9**).

Cities with the highest levels were clustered in east-central China and the Indo-Gangetic Plain. Many cities in low- and middle-income countries lack available measurements, but where data is available, 98 per cent of cities exceed the WHO guidelines for  $\text{PM}_{2.5}$  or  $\text{PM}_{10}$ , compared with the 56 per cent of cities in high-income countries with available data (WHO 2016b).

**Figure 5.9: Annual average  $\text{PM}_{10}$  levels for megacities of more than 14 million inhabitants with available data for the period 2011-2015**

Source: WHO (2016b).

Traffic, residential fuel burning, electricity generation, industry and agriculture all contribute to urban air pollution, although the contribution of different sectors in individual cities can vary significantly (Karagulian *et al.* 2015). In growing cities across Africa, Asia and other developing regions, there has been an unprecedented rapid increase in the number of vehicles, driven by population growth and economic development (e.g. Adiang *et al.* 2017). It is projected that by 2030 there will be 41 megacities (population greater than 10 million), the majority in developing countries (United Nations 2016b). Impacts of the pollution from megacities extends far beyond the urban area with effects at local, regional and global scales (Ang'u, Nzioka and Mutai 2016; WHO 2016b).

Air pollution observed in any given location may be comprised of contributions from local, regional and even global sources (Figure 5.10).

Better global models, additional monitoring and field studies, and accumulated observations from satellite-based instruments have improved our understanding of the processes and trends that drive such long-range transport of pollution. However, quantifying the absolute contributions of distant sources to observed values on a given day remains challenging. Data assembled for the Tropospheric O<sub>3</sub> Assessment Report (TOAR) demonstrates that recent trends in peak values upon which most health-based standards are founded are strongly decreasing in North America and

Europe, and strongly increasing in parts of East Asia. However, for summer daytime average O<sub>3</sub> concentrations, the trends are more mixed in North America and Western Europe, with some sites showing significant increases (Chang *et al.* 2017; Schultz *et al.* 2017). This finding is consistent with observations of increasing 'background' O<sub>3</sub> above the boundary layer throughout the Northern Hemisphere (Task Force on Hemispheric Transport of Air Pollution 2010; Parrish *et al.* 2014). The observed increasing trend in global tropospheric O<sub>3</sub> from 1980 to 2010 may be due primarily to an equatorward shift in the distribution of global precursor emissions, the effect of which is larger than the increase in global methane and the total mass of other precursor emissions combined (Zhang *et al.* 2016).

The largest source of particulate matter in the atmosphere globally, on an annual basis, is windblown sand and dust. A 'dust belt' extends from the west coast of North Africa, over the Mediterranean Basin, the Middle East, Central and South Asia, to Mongolia and China (see Figure 5.11). This encompasses both natural areas, such as the Sahara and Taklamakan deserts, as well as agricultural areas. Outside the dust belt, sand and dust storms (SDS) are less prevalent; however, SDS can have important local impacts in central Australia, Southern Africa (Botswana and Namibia), the Atacama in South America, and the North America Great Basin (UNEP, WMO and UNCCD 2016). People influence dust sources through land clearing and land management practices and other influences on

**Figure 5.10: Model estimates of the sources of PM<sub>2.5</sub> observed in several cities in each of three countries shows local PM<sub>2.5</sub> concentrations are strongly influenced by secondary particles from transboundary sources. The source of emissions is divided into natural, international (emitted outside the country), national (emitted within the country but outside the urban area), urban (emitted within the city) and street (emitted within the immediate vicinity of the observation) and interim targets**

desertification (see Section 8.4.2). UNEP, WMO and UNCCD (2016) concluded that there has been little change in the frequency and severity of SDS in North Africa, the Middle East and South America over the last 30 years, but significant increases have been observed in North America, Central Asia and Australia. Klingmuller *et al.* (2016) found an increasing trend in dust over large parts of the Middle East during the period 2001 to 2012 that is correlated with climatic changes.

Transported dust contributes to a wide range of impacts: it affects climate and precipitation patterns; fertilizes distant forests and oceans; contributes to human respiratory ailments; and spreads human, animal and plant pathogens far downwind of the source region. Within the source region, dust storms may damage infrastructure, interrupt transportation and communication systems, and cause air and road traffic accidents. To better understand, forecast and mitigate these impacts, WMO has established a global Sand and Dust Storm Warning Advisory and Assessment System (SDS-WAS) (UNEP, WMO and UNCCD 2016; WMO 2017b).

Fires, primarily associated with land clearing or lightning, are another large contributor to transboundary pollution. In South-East Asia, perennial forest and peatland fires associated, primarily with slash-and-burn agriculture, intensify during dry seasons (Page and Hooijer 2016; Wijedasa *et al.* 2017). In 2015, fires blanketed the region with smoke, leading to an estimated 100,000 premature deaths associated with air pollution exposure, mostly in Indonesia (Kopplitz *et al.* 2016) (see Section 12.2.5). Boreal forest fires in Siberia, Canada and Alaska contribute to the deposition of BC and other particles in the Arctic, darkening the surface of snow and ice and accelerating melting (Arctic Monitoring and Assessment Programme [AMAP] 2011; AMAP 2015).

### 5.3.2 Persistent bioaccumulative toxic substances

Gaseous elemental Hg is a global pollutant with the highest concentrations in East, South and South-East Asia, and in the artisanal gold mining regions of Equatorial Africa and South America (see **Figure 5.12**) (UNEP and AMAP 2018).

Concentrations of POPs that are regulated and monitored under the Stockholm Convention have been reduced in Europe, North America, and Asia and the Pacific (UNEP 2014a; UNEP 2014b; UNEP 2015a; UNEP 2015b).

Measurements of regulated POPs in Arctic air and biota show predominantly downward trends for substances that have been banned for more than 20-30 years in developed countries, but the rate of their decrease has slowed (Hung *et al.* 2016). Trends of POPs in the Arctic appear to be sensitive to changes in climate, due to increased volatilization from sources (AMAP 2014, Ma *et al.* 2011) and to changes in Arctic land-use and emission patterns, such as increases in mining and shipping (UNEP and AMAP 2011) (see also Sections 4.3.2 and 4.3.3). Although Antarctica is the Earth's continent least subject to direct human impact, low but sometimes significant contamination levels can be found there (Vecchiato *et al.* 2015). Concentrations of PAHs and PCBs in Antarctic snow have decreased over recent decades (Vecchiato *et al.* 2015).

Trends for many new PBTs, however, are not yet established, although baseline data have become available in some regions, such as Europe (UNEP 2015a). As some POPs have been regulated or banned, other unregulated PBTs have emerged as substitutes and are widely used in consumer and household items (e.g. furniture and electronics) and construction materials (Lee *et al.* 2016; Rauert *et al.* 2016). The growing

Circles show values observed in ground-based monitoring

Source: UNEP and AMAP (2018).

number of listed POPs and candidate substances presents a resource pressure for existing monitoring programmes (UNEP 2015a). The emission, transport and environmental fate of new unregulated PBTs differs from regulated POPs, further challenging their assessment.

### 5.3.3 Stratospheric O<sub>3</sub> and ultra-violet radiation

Perennial ground-based *in situ* observations of ODS show a clear decline since the implementation of the Montreal Protocol (Newman *et al.* 2007; Engel *et al.* 2018). However, the decreasing trend slowed down by about 50 per cent after 2012 for trichlorofluoromethane (CFC-11) (Montzka *et al.* 2018). There are indicators that the stratospheric O<sub>3</sub> layer is starting to recover. Total atmospheric column O<sub>3</sub> declined over most of the globe during the 1980s and early 1990s, but has remained stable since 2000, and there are indications of an increase in global-mean total column O<sub>3</sub> over 2000-2013 (Figure 5.13) (WMO 2014). Since around 2000, measured concentrations of O<sub>3</sub> in the upper stratosphere show an increasing trend, and modelling results indicate that decreasing ODSs and increasing GHGs, which increases stratospheric ozone by cooling the stratosphere, contributed equally to the increase in upper stratospheric ozone (WMO 2014; Harris *et al.* 2015; Chipperfield *et al.* 2017). Over Antarctica, positive trends for 2001-2013 were found for O<sub>3</sub> concentrations in the lower stratosphere (about 10-20 km) for austral summer and for total column O<sub>3</sub> for spring and summer (Kuttippurath and Nair 2017; Solomon *et al.* 2017). For the mid-latitudes (60°S and 60°N), there is no

clear indication of O<sub>3</sub> recovery for reasons that are not clear (Ball *et al.* 2018). As ODS concentrations continue to decline throughout the 21st century, stratospheric O<sub>3</sub> concentrations are expected to rise, though the trends will be increasingly dominated by effects from rising GHG concentrations; thus, the time frame for stratospheric O<sub>3</sub> to recover to 1960 levels is uncertain (Chipperfield *et al.* 2017).

Changes in ultraviolet (UV) radiation at the Earth's surface in response to the recovery of stratospheric O<sub>3</sub> have not yet been documented, because such changes are still masked by varying attenuation of UV radiation by O<sub>3</sub>, clouds, aerosols and other factors (Bais *et al.* 2018).

### 5.3.4 Climate change

In 2016, global averaged concentrations of CO<sub>2</sub>, CH<sub>4</sub> and N<sub>2</sub>O reached 403.3±0.1 ppm, 1853±2 ppb and 328.9±0.1 ppb, respectively, corresponding to 145 per cent, 257 per cent and 122 per cent above pre-industrial levels (WMO 2017c). The global CO<sub>2</sub> growth rate from 2015 to 2016 was the largest of the last 30 years (partly driven by El Niño) and the CO<sub>2</sub> concentration was the highest in at least the last 800,000 years. CH<sub>4</sub> concentrations plateaued during 1999-2006 but have been increasing since then. Studies point to a variety of different processes driving the change in CH<sub>4</sub>, mainly changes in anthropogenic sources, permafrost melting or wetland emissions (Dean *et al.* 2018). N<sub>2</sub>O concentrations have been increasing steadily since the mid-1980s. Concentrations of CFC

**Figure 5.13: Vertical profiles of annual mean O<sub>3</sub> trends over 35°-60°N averaged over all available observations (black) for the periods of stratospheric ODS decline (left) and ODS increase (right), with the corresponding modelled trends for ODS changes only (red), GHG changes only (blue) and both together (grey)**

Note: The ±2 standard error uncertainty range for the trends is shown by the horizontal bars for the observations and by the grey shading for the all-changes modelled trend.

Source: WMO (2014).

replacements, HCFCs and HFCs, which are potent GHGs, have been increasing exponentially since 2005, though these remain low overall and currently contribute to less than 4 per cent combined of the radiative forcing due to all GHGs. According to the National Oceanic and Atmospheric Administration Annual Greenhouse Gas Index (AGGI), radiative forcing by long-lived GHGs increased by 78 per cent between 1979 and 2016, with CO<sub>2</sub> accounting for about 72 per cent of this increase.

Since 1901 almost the whole globe has experienced surface warming, and it is extremely likely that anthropogenic activities caused more than half the observed increase in global mean surface temperature since the mid-20th century (Bindoff *et al.* 2013). The global mean surface temperature increase over the 1901–2012 period (see **Figure 4.2**) was approximately 0.89°C, but some regions experienced warming of greater than 2°C (Hartmann *et al.* 2013).

Trends in precipitation are less clear and differ by locations. In general, dry areas are becoming drier, and wet areas are becoming wetter, but multiple exceptions exist (Trenberth 2011; IPCC 2014; Feng and Zhang 2015). For tropical land areas, observations show a decreasing trend from the mid-1970s to mid-1990s and an increasing trend the following decade, resulting in no significant overall trend from 1951 to 2008 (Hartmann *et al.* 2013). A statistically significant increase in precipitation occurred from 1901 to 2008 for the northern mid-latitudes (30°N to 60°N) land areas; in contrast, there is only limited evidence of a long-term increase in the southern mid-latitudes (Hartmann *et al.* 2013). Observed changes in the latitudinal distribution of precipitation over land are suggestive of human influence; however, the results are still inconclusive, due to incomplete data and model uncertainties (Bindoff *et al.* 2013).

Climate change can also impact atmospheric circulations and features at global and regional levels. Observations indicate a widening of the tropical belt, a poleward shift of storm tracks and jet streams, and a contraction of the northern polar vortex since the 1970s are likely (Hartmann *et al.* 2013). Stratospheric O<sub>3</sub> depletion and GHG warming may have contributed to the poleward shift of the southern Hadley cell and positive trend in the Southern Annular Mode, which characterizes the north-south movement of the belt of westerly winds that circles Antarctica, during the austral summer (Bindoff *et al.* 2013). Attribution of anthropogenic influence on the poleward shift of the Hadley cell in the Northern Hemisphere is less certain (Bindoff *et al.* 2013). While many studies have indicated changes in the El Niño–Southern Oscillation (ENSO) and monsoon circulations, there are large observational and modelling uncertainties such that there is low confidence that changes, if observed, can be attributed to anthropogenic activities (Bindoff *et al.* 2013).

There is increasing evidence that climate change has led to changes in the frequency and intensity of extreme events since the mid-20th century (Trenberth 2011; Hartmann *et al.* 2013; Alexander 2016). It is likely that the frequency of extreme warm days has increased in North America, Central America, Europe, Southern Africa, Asia and Australia, and the frequency of heat waves has increased in Europe, Australia and across large parts of Asia (Hartmann *et al.* 2013). Observations have shown a general increase in heavy precipitation at the global scale (Trenberth 2011; Hartmann *et al.* 2013). Regionally, it is likely

that the frequency or intensity of heavy precipitation events has increased in North America, Central America and Europe, and it is virtually certain that there has been an increase in the frequency and intensity of the strongest tropical cyclones in the North Atlantic basin since the 1970s (Hartmann *et al.* 2013). For drought, the frequency and intensity likely have increased in the Mediterranean and West Africa, and likely have decreased in central North America and north-west Australia (Hartmann *et al.* 2013).

Air pollution, stratospheric O<sub>3</sub> depletion, persistent pollutants and climate change are interlinked problems (see **Figure 5.1**). Climate warming agents such as BC, tropospheric O<sub>3</sub>, CH<sub>4</sub> and HFCs have a relatively short lifetime in the atmosphere compared with long-lived GHGs and are referred to as short-lived climate pollutants (SLCPs) (Haines *et al.* 2017). Tropospheric O<sub>3</sub> contributes to warming directly as a GHG. However, O<sub>3</sub> also contributes to warming by impairing vegetation growth and decreasing plant uptake of CO<sub>2</sub> (Ainsworth *et al.* 2012). BC has a warming effect both in the atmosphere and when deposited on snow and ice. Decreasing emissions of SLCPs can decrease warming in the near term, which may be essential for achieving near-term climate targets or avoiding climate tipping points (Shindell *et al.* 2017). However, decreasing emissions of SLCPs in the near term needs to be combined with mitigation of long-lived GHGs, which dominate climate forcing over the long term (UNEP 2017c).

Other PM constituents (e.g. sulphates and nitrates) also affect climate and may cool the climate by scattering solar radiation. PM also affects climate indirectly by affecting cloud formation, leading to changes in cloud reflectivity, cloud distribution and precipitation patterns. There is still a significant amount of uncertainty on the net radiative effects of aerosols (Fuzzi *et al.* 2015).

Through its impact on synoptic and local-scale meteorology, climate change impacts air pollution and PBT concentrations in multiple, non-linear ways (UNEP and AMAP 2011; Fiore, Naik and Leibensperger 2015). Higher temperatures can increase the chemical reaction rates involving O<sub>3</sub> formation or reduce PM concentrations as components volatilize (Megaritis *et al.* 2013; Czernecki *et al.* 2016). Higher temperatures also increase primary emissions of POPs that can volatilize and secondary emissions by revolatilizing previously deposited POPs (Ma *et al.* 2011). Because particle-bound POPs are more efficiently removed from the atmosphere via deposition, semi-volatile POPs may last longer in the atmosphere at higher temperatures and be transported further from source regions. Higher temperatures may also increase degradation of POPs (Ma *et al.* 2011). Reduced cloud cover promotes the formation of O<sub>3</sub> by increasing photolysis rates (Na, Moon and Kim 2005). Higher temperatures and light intensity can also increase emissions of biogenic NMVOC (Guenther *et al.* 2012), which are O<sub>3</sub> and PM precursors. At the same time, higher temperatures and water stress lower stomatal uptake of O<sub>3</sub> and thus reduce O<sub>3</sub> deposition (Solberg *et al.* 2008; Huang *et al.* 2016). More rain reduces pollution by washing out PM and other pollutants. Extreme events such as heat waves and drought increase risks of high PM pollution associated with wildfires (Bowman *et al.* 2017) and dust (Achakulwisut, Mickley and Anenberg 2018). Extreme events such as floods and storms can also impact the remobilization and bioavailability of POPs (Ma *et al.* 2011).

Meteorological parameters that affect air quality often covary with and depend on synoptic-scale or other larger-scale phenomena. For example, surface  $O_3$  and PM concentrations are strongly influenced by ventilation and dilution, which are governed by winds and boundary-layer height and are often correlated with temperature and humidity. A decline in the number of summertime mid-latitude cyclones travelling across North America since 1980 has been associated with increases in stagnation and  $O_3$  pollution episodes in the eastern United States of America, offsetting some of the air quality improvement in the north-eastern United States of America from reductions in anthropogenic emissions (Leibensperger, Mickley and Jacob 2008). Extreme wintertime stagnation and pollution episodes in eastern China have been associated with melting sea ice in the Arctic during the preceding autumn and increased snowfall across Siberia during early winter (Zou *et al.* 2017).

## 5.4 Impacts

Activities that generate emissions threaten human health and well-being, food security and ecosystems. This section focuses on the direct impacts of changing atmospheric composition.

### 5.4.1 Human health

Exposure to air pollution outdoors and indoors, temperature extremes, airborne pathogens and allergens, and ultraviolet radiation directly affect human health. The following focuses on air pollution effects due to anthropogenic emissions.

#### **Air Pollution**

Exposure to indoor and outdoor air pollution was responsible for 6 million (Global Burden of Disease [GBD] Risk Factor Collaborators 2017) to 7 million (WHO 2018) premature deaths in 2016. The GBD Study estimated that long-term exposure to ambient PM was responsible for between 3.6 and 4.6 millions of those premature deaths and between 95 and 118 million years of healthy life lost from heart disease, stroke, lung cancer, chronic lung disease and respiratory infections (Cohen *et al.* 2017; GBD Risk Factor Collaborators 2017; HEI 2018). Consequently, exposure to ambient  $PM_{2.5}$  is the highest environmental risk factor for the global burden of disease and sixth among all risk factors in terms of disability-adjusted life years lost, behind high blood pressure, smoking, low birth weight, high levels of blood sugar and high body mass index (GBD Cancer Collaboration 2017). The estimates of premature deaths underestimate the total number of individuals affected, because air pollution has potential effects on everyone who breathes the air, rather than being the sole reason for early death in a small subset of the population (Committee on the Medical Effects of Air Pollutants [COMEAP] 2010).

Even brief periods (minutes to hours) of exposure to high concentrations of pollutants can have significant health impacts (WHO 2006), and episodes of unusually high air pollution attract public concern (e.g. Vidal 2016; Safi 2017). However, the greatest damage to public health is associated with long-term exposure – living in areas of high annual average exposure (HEI 2017). Importantly, there is no known safe level of annual average  $PM_{2.5}$  exposure (WHO 2013).

About 43 per cent of the world's population, primarily in low-income countries, uses biomass for heating and cooking. The resulting indoor and outdoor air pollution contributes to acute lower respiratory infections (ALRTI) and pneumonia among children, and chronic obstructive pulmonary disease (COPD) and lung cancer among adults (WHO 2007; Sumpter and Chandramohan 2013; WHO 2018). The GBD Study attributed between 66 and 88 million disability-adjusted life years (DALYs) lost, and between 2.2 and 3.0 million premature deaths in 2016 to household air pollution (GBD Risk Factor Collaborators 2017), whereas WHO estimated the burden to be approximately 3.8 million premature deaths (WHO 2018).

An additional 0.09 to 0.38 million deaths in 2016 from chronic lung disease were attributed to ambient ground-level  $O_3$  exposure (GBD Risk Factor Collaborators 2017). Associations of mortality with other gases are well established, notably  $NO_2$  (a marker of traffic pollution) and  $SO_2$  (a marker of industrial pollution) (WHO 2013). Because these are markers of mixtures, it is unclear to what extent effects associated with them are caused by the gases themselves or by correlated pollutants (WHO 2013; COMEAP 2018).

© Shutterstock/TonyV3112

The number of deaths attributable to air pollution varies widely among countries, reflecting different pollution levels as well as differences in population size, demographics, underlying rates of disease and other socioeconomic characteristics (Figure 5.14)

Between 2010 and 2016, deaths attributable to ambient  $PM_{2.5}$  exposure increased by 11 per cent globally, due to increased air pollution, as well as growth and ageing of the population. In 2016, 95 per cent of the world's population lived in areas with levels of  $PM_{2.5}$  exceeding the WHO air quality guideline (HEI 2018). While mortality attributable to  $PM_{2.5}$  has declined in Western Europe and North America, many other regions have seen sharp increases. Deaths attributable to ground-level  $O_3$ , though much fewer, have increased nearly 60 per cent globally between 1990 and 2015, with increases in some countries as high as 250-400 per cent (HEI 2017).

In addition to premature mortality, air pollution contributes to a wide range of chronic and acute diseases, especially cardiovascular (Brook *et al.* 2010; McCracken *et al.* 2012) and respiratory disease (American Thoracic Society 2000). Studies suggest associations between air pollution and other diseases such as diabetes (Eze *et al.* 2015); adverse birth outcomes (Stieb *et al.* 2012; Li *et al.* 2017) including premature births, low birth weight (Fleischer *et al.* 2014) and birth defects (Farhi *et al.* 2014); and neurological ailments, including dementia (Calderon-Garciduenas and Villarreal-Rios 2017). Emerging research highlights the potential interactions between air pollution and airborne pathogens and allergens (Hussey *et al.* 2017; Liu *et al.* 2018).

People who are elderly, very young, with pre-existing cardio-respiratory diseases or of low socioeconomic status are most susceptible to air pollution (Sacks *et al.* 2011). Women and children have higher exposures to air pollution indoors, where cooking and heating with solid fuels is the major source

(Smith *et al.* 2014). There is increasing evidence that indoor smoke contributes to cataracts, the leading cause of blindness worldwide (Clougherty 2010; Sacks *et al.* 2011; Global Alliance for Clean Cookstoves 2014; Villeneuve *et al.* 2015; WHO 2016b).

The economic impacts of life years lost, increased health care and lost worker productivity due to air pollution are considerable. Premature mortality due to ambient and household air pollution in 2013 was estimated to cost the world's economy US\$ 5.1 trillion in welfare losses (World Bank and Institute for Health Metrics and Evaluation 2016). This is equivalent to the 2013 gross domestic product (GDP) of Japan. WHO (2015) estimated that air pollution in Europe in 2010 cost US\$ 1.575 trillion per year. In 2011, the US EPA estimated emission controls implemented as a result of the 1990 Clean Air Act Amendments avoided US\$ 1.3 trillion in damages in 2010 (US EPA 2011). The impact of  $PM_{2.5}$  air pollution on the labour force in China in 2007 was estimated to create economic losses of 346 billion yuan (approximately 1.1 per cent of GDP) (Xia *et al.* 2016). A recent OECD analysis estimated the combined cost of ambient and household air pollution in Africa to be US\$ 450 billion in 2013 (Roy 2016).

Asia had the highest absolute number of deaths in 2016 attributable to  $PM_{2.5}$  exposure, due to its large populations and high levels of industrial activity. However,  $PM_{2.5}$  exposures have begun to decline in China but are increasing in parts of South Asia (HEI 2018). Asian countries also bear the largest burden of air pollution caused by the production of goods consumed in other regions of the world, primarily Western Europe and North America. For example, 97 per cent of  $PM_{2.5}$  related deaths in East Asia were associated with emissions in East Asia, but only 80 per cent were associated with goods or services consumed in East Asia. Consumption in Europe and Russia and in North America of goods made in East Asia were estimated to contribute 7 per cent and 6 per cent, respectively, to the  $PM_{2.5}$  mortality burden in East Asia (Zhang *et al.* 2017) (Figure 5.15).

Figure 5.14: Deaths per 100,000 people in 2016 attributable to ambient  $PM_{2.5}$  air pollution; age-standardized data

Age standardization allows the estimates to be compared for countries with different age distributions. Note that these estimates do not include deaths attributable to exposure to household air pollution

### Stratospheric ozone depletion

The health risks of stratospheric O<sub>3</sub> depletion occur as a result of increased levels of biologically damaging wavelengths of UV radiation reaching the Earth's surface. Although some exposure to UV is necessary, too much exposure damages the skin and eyes and can cause immune suppression. Impacts include sunburn, keratinocyte (previously called non-melanoma) cancers, cutaneous malignant melanoma (CMM), Merkel cell carcinoma, photoconjunctivitis, photokeratitis (e.g. snow blindness), cataracts, pterygium and conjunctival melanoma.

In recent decades, most countries with predominantly fair-skinned populations have experienced a steady increase in the incidence rates of CMM which is responsible for about 80 per cent of the deaths due to skin cancer (Lucas *et al.* 2015). Excessive exposure to UV radiation accounts for 60-90 per cent of the risk for CMM (Olsen, Carroll and Whiteman 2010; WHO 2004). Increasing incidence rates of CMM and other UV-related adverse health impacts are unlikely to be due to changes in UV exposure due to stratospheric O<sub>3</sub> depletion, but rather to increases in risky sun exposure behaviour (Lucas *et al.* 2015). However, without the Montreal Protocol, incidence of skin cancer may have been 14 per cent greater, affecting 2 million people by 2030 (van Dijk *et al.* 2013).

### Climate change

Over the coming decades to centuries, adverse health effects from climate change are forecast to greatly exceed any potential health benefits (Smith *et al.* 2014; Watts *et al.* 2017). The effects of climate change on human health can be classified as direct (e.g. heat waves, storms), less direct (e.g. changes in disease-vector ecology, reductions in water supply, or exacerbation of air pollution episodes) and diffuse (Butler 2014; Melillo, Richmond and Yohe 2014). The category of diffuse effects could have the largest burden of disease through means such as conflict (Kelley *et al.* 2015), migration (Piguet, Pecoud and de Guchteneire eds. 2011) and famine. Mental health effects arise from all three categories (e.g. post-traumatic stress disorder).

The health impacts of a changing climate will be inequitably distributed globally. Climate change and increasing climate variability "worsen existing poverty, exacerbate inequalities, and trigger both new vulnerabilities and some opportunities for individuals and communities" (IPCC 2014, p. 796).

Buildings and roads retain heat more than rural landscapes and depress humidity, creating urban heat islands. In northern mid-latitudes and subtropics, nights are up to 4°C warmer and

10-15 per cent drier in urban areas compared with surrounding rural areas. In northern Africa, the number of nights with exceptional heat stress is around ten times higher in urban areas than in rural areas (Fischer, Oleson and Lawrence 2012).

#### 5.4.2 Food security

The Food and Agriculture Organization of the United Nations (FAO 2008) describes four dimensions of food security: availability, related to quantity; access, including affordability; utilization, related to meeting nutritional needs and food safety; and stability, related to the temporal variation in the other dimensions.

**Availability:** Current levels of ground-level O<sub>3</sub> decrease yields of key staple crops – including wheat, soybean, maize and rice – by 2-15 per cent depending on crop types and locations (Feng and Kobayashi 2009; Van Dingenen *et al.* 2009; Fishman *et al.* 2010; Avnery *et al.* 2011). Global estimates of damage are uncertain because different cultivars of crops have different sensitivities and not all crops have been studied. The economic implications of loss of crop productivity are substantial. For example, elevated O<sub>3</sub> concentrations in the United States of America reduce maize and soybean production by about 10 per cent and 5 per cent, respectively, at a cost of US\$9 billion annually (McGrath *et al.* 2015).

Climate change already affects crop production through changes in average and extreme temperatures and precipitation, the spread and impacts of invasive weeds and pests and deforestation. Although increased CO<sub>2</sub> fertilization (see Section 4.4.3) is thought to offset negative impacts, the interactions between changes in CO<sub>2</sub>, O<sub>3</sub>, nitrogen, water availability and temperature are still not well understood (Schlenker and Roberts 2009; Porter *et al.* 2014).

Yields in tropical countries are expected to suffer the most serious impacts, while some temperate regions may benefit from higher yields, expansion of productive areas and longer growing seasons (though these benefits may be offset by increasingly frequent extreme events, temperature and water stresses and ineffective adaptations) (Schmidhuber and Tubiello 2007; Gornall *et al.* 2010; Porter *et al.* 2014). In short, the impact of climate change on crop production will be felt most heavily in developing countries where large numbers of people depend on agriculture for their livelihoods, food insecurity is high and adaptive capacity low. Climate change impacts on the availability and distribution of aquatic species are also expected to disproportionately affect developing countries (see Section 7.3.2).

Higher temperatures are likely to adversely affect livestock productivity by changing the availability of pasture, fodder crops and water (Andre *et al.* 2011; Renaudeau *et al.* 2011; Porter *et al.* 2014). The impacts of climate change on livestock diseases remain difficult to predict and highly uncertain (Mills, Gage and Khan 2010; Tabachnick 2010).

**Access:** Climate change exerts upward pressure on global food prices (Porter *et al.* 2014), disproportionately affecting poor consumers who may spend a significant proportion of their income on food, with implications for health and nutrition (Springmann *et al.* 2016). Women and girls disproportionately suffer from both the health consequences of nutritional

deficiencies and the greater burdens of caregiving for others who are ill (WHO 2014; FAO 2016).

**Utilization:** Higher temperatures and higher CO<sub>2</sub> levels are associated with lower protein content of grains (Porter *et al.* 2014; Feng *et al.* 2015) and reduced micronutrient content of grains and legumes (Myers *et al.* 2014).

The nutritional content and safety of food supply is affected by pollution, primarily by PBTs, including Hg and POPs. Hg can travel long distances in the air and water, bioaccumulate and biomagnify up food chains, reaching levels that can be dangerous to the health of ecosystems and humans (Gibb and O'Leary 2014; Sundseth *et al.* 2017). Concentrations of methylmercury in the blood of populations that consume top marine predators, such as indigenous Arctic people, are among the highest recorded globally, giving rise to serious health concerns (UNEP 2013a; UNEP 2013b). Hg is toxic to the central nervous system (CNS) leading to cognitive and motor dysfunction (Karagas *et al.* 2012; Antunes dos Santos *et al.* 2016; Sundseth *et al.* 2017). Hg exposure also increases the risk of cardiovascular diseases, causes kidney damage, adversely affects the reproductive, endocrine and immune systems, and leads to premature death (Rae and Graham 2004; AMAP 2009; Rice *et al.* 2014).

Similarly, POPs and other PBTs can travel long distances and bioaccumulate up food chains (e.g. Gibson *et al.* 2016; Ma, Hung, and Macdonald 2016). A wide range of health effects has been associated with exposure to POPs, including changes to the reproductive, endocrine, immunologic and neurologic systems, cancer, dermal and ocular changes, and reduced birth weight (Damstra 2002; El-Shahawi *et al.* 2010; Fry and Power 2017). The exposure of pregnant and breastfeeding women to POPs is of particular concern, as POPs can cross the placenta and the blood-milk barrier, which may increase the risk of adverse developmental outcomes in children (Vizcaino *et al.* 2014; Women in Europe for a Common Future and Women International for a Common Future 2016).

Little is known about the potential health effects of some chemicals that have substituted for banned POPs, such as non-polybrominated diphenyl ether (PBDE) organophosphate flame retardants. Human exposure to such flame retardants in the United States of America has been observed to be increasing over the last decade (Hoffman *et al.* 2017).

**Stability:** The increasing frequency and severity of extreme weather caused by climate change will have serious consequences for the stability of food prices and food supply, such as the wheat harvest failure and price spike experienced following the 2010 Russian heat wave (Otto *et al.* 2012; Porter *et al.* 2014). Droughts, floods and other weather-related disasters can lead to acute, localized food crises, particularly in countries with pre-existing vulnerabilities such as high levels of poverty and undernutrition. For example, climate change contributed to the drought that led to the 2011 East African food crisis and ultimately contributed to famine in Somalia (Bailey 2013; Lott, Christidis and Stott 2013; Coghlan *et al.* 2014). If transport infrastructure supporting exports from major crop-producing regions is disrupted by acute weather shocks, the impacts on food security could be more widespread (Bailey and Wellesley 2017).

### 5.4.3 Ecosystems

Air pollution, climate change, UV radiation and PBTs all have effects on the health of natural ecosystems and wildlife. These adverse impacts in turn affect the services provided to humans by those ecosystems, or 'nature's contribution to people' (NCP) (Diaz *et al.* 2018).

Since the 1970s, international attention has focused on air pollution in the form of wet and dry deposition of sulphur and nitrogen, often referred to as 'acid rain', which led to acidification of soils and fresh water, and damage to vegetation and fish kills. In Asia and Africa, significant increases and decreases in sulphur deposition have been observed depending on location (Vet *et al.* 2014). In Western Europe and eastern North America, after decades of declining sulphur emissions and deposition levels, acidification is declining or slowing, and some forests and lakes are showing signs of recovery (Maas and Grennfelt eds. 2016). As sulphur emissions have decreased due to the implementation of emission controls, recent assessments have focused attention on the effect that humans have had on the global nitrogen cycle and its implications.

Human activity, mainly through combustion and fertilizer production, are responsible for as much nitrogen fixation as natural and unmanaged ecosystems, significantly altering the nitrogen cycle from its pre-industrial state (Fowler *et al.* 2015). Since 2000, nitrogen deposition has decreased in North America and Europe and increased in Africa and Asia, directly corresponding to decreases of  $\text{NO}_x$  and increases in  $\text{NH}_3$  continent-wide emissions (Zhao *et al.* 2017). Nitrogen deposition exceeds critical loads over large parts of Europe and the area of exceedance has shown little change in recent decades (Hettelingh *et al.* 2015). High levels of nitrogen deposition contribute to the eutrophication of aquatic ecosystems and can affect terrestrial plant communities, possibly favouring dominant species, which in turn affects insects, birds and other animals. The loss of biodiversity due to excess nitrogen deposition is very likely to be occurring in many parts of the world, although the impacts have not been well quantified. Changes in climate, land use and other global changes will continue to alter the nitrogen cycle in the future, with consequences for ecosystems and human health (Fowler *et al.* 2015).

Marine ecosystems are also affected by air pollution, climate change and PBT pollution, for instance through the distribution of oceanic dissolved nutrients and oxygen (York 2018). Human activity is now increasing the inputs of all fixed nitrogen to the oceans by about 50 per cent (more in local hotspots near high emission regions in South-East Asia, Europe and North America) and atmospheric transport is now the dominant route contributing anthropogenic nitrogen into the open ocean beyond the continental shelf (Joint Group of Experts on the Scientific Aspects of Marine Environmental Protection [GESAMP] 2018). Harmful algal blooms in turn can contribute to respiratory health impacts through airborne transmission of aerosols (Centers for Disease Control and Prevention 2017).

Ozone exposure can affect plant growth, flowering, pollination and susceptibility to pathogens, with impacts on species composition and biodiversity (Fuhrer *et al.* 2016). Critical load thresholds have been identified for some terrestrial ecosystems

(International Cooperative Programme on Effects of Air Pollution on Natural Vegetation and Crops 2017), but there are many ecosystems for which  $\text{O}_3$  sensitivity is poorly understood.

The full extent of PBT exposure and their biological effects on wildlife and natural ecosystems is still not well known and is an area of active research (AMAP 2017). However, given the widespread presence of PBTs in the environment, the potential exists for long-term damage to food chains and ecosystem functions especially in sensitive areas, such as the Arctic (AMAP 2011; AMAP 2016; AMAP 2017).

### 5.4.4 Social well-being

Beyond the impacts on human and ecosystem health and food security, changes in the atmosphere have negative impacts on social well-being, or welfare.

Air pollution degrades materials and coatings, decreasing their useful life and generating costs for cleaning, repair and replacement. When the materials affected are structures or objects of cultural significance, the damage can be priceless (Watt *et al.* eds. 2009). In Europe, visible pollution damage to cultural heritage sites and artworks was highlighted as a justification for air pollution control policies (Di Turo *et al.* 2016; Maas and Grennfelt eds. 2016). In India, the government has taken steps to protect, in addition to public health, the white marble Taj Mahal, which has become discoloured over time due to high levels of PM, possibly from the open burning of municipal solid waste (Bergin *et al.* 2015; Raj *et al.* 2016).

Sand and dust storms, fires and extreme weather events all create disruptions to society, transportation and economic activity. Such events can be a drag on a local economy and may also drive dislocations and migration (Hanlon 2016). In the short term, increased pollution levels affect worker productivity. These effects are not limited to outdoor workers or to extreme pollution levels (Chang *et al.* 2016; Zivin and Neidell 2018). In the longer term, elevated pollution exposures have been associated with poor educational and labour-market performance, creating a long-term human capital deficit (Zivin and Neidell 2018).

## 5.5 Response: policies and governance

A wide variety of governance approaches and policy instruments have been used to help mitigate the sources and impacts of air pollution, climate change, stratospheric  $\text{O}_3$  depletion and PBTs, including the following.

- ❖ **Planning regimes**, strategies or action plans designed to achieve ambient air quality standards or objectives or attain emission ceilings, combined with analyses and environmental impact assessments.
- ❖ **Command and control**, including technology, emissions or ecosystem restoration standards; record-keeping and reporting requirements, or limits on manufacture, trade or use of specific chemicals or products; each of which are implemented through permitting and enforcement programmes.
- ❖ **Market interventions**, including economic instruments, such as taxes, fees or markets for tradable emission rights, as well as loans and subsidies.

- ❖ **Public information**, including product labelling, air quality forecasting, near real-time observations and training.
- ❖ **Cooperative frameworks**, including international agreements and voluntary sectoral standards or initiatives.

The effectiveness of specific examples of these policies is explored further in Chapter 12.

Different governance approaches have been adopted at local, provincial, country and international scales depending on the specific institutional, economic, technological and political contexts. Often multiple complementary approaches are deployed simultaneously to address a single issue or source. Different mixes of approaches may be used to address similar issues, even in a single jurisdiction.

The existence and extent of implementation of air-related policies also vary widely based on differences in institutional capacity and culture in different regions of the world and at different spatial scales. In some regions, such as North America and Europe, there are well-developed, federated systems of national, provincial and local policies and enforcement programmes designed to achieve common policy objectives. In other regions, international agreements or national legislation may exist, but implementation and enforcement are weak due to a lack of institutional capacity at the national or subnational scale. In some regions, city governments are developing the primary policy response to these issues, with simultaneous benefits for other parts of their countries.

Climate change, stratospheric O<sub>3</sub> depletion and PBTs have been recognized as shared global problems. **Table 5.2** lists some global environmental agreements that have been developed to motivate, enable and coordinate ongoing efforts to address these challenges. These set out common objectives

and obligations, which are implemented through different policies developed at national to local levels. One of the most successful global agreements is the Vienna Convention and Montreal Protocol to address stratospheric O<sub>3</sub> depletion, which in 2009 became the first United Nations convention to be ratified by all United Nations member states. The most recent amendment to the Montreal Protocol, the 2016 Kigali Amendment, is designed to limit the impact of ODS substitutes on climate change.

Adopted in 1992, the United Nations Framework Convention on Climate Change (UNFCCC) has led to the negotiation of a series of protocols and agreements on “common but differentiated responsibilities” to address GHG emissions (United Nations 1992). The UNFCCC divides countries into developed (Annex I) and developing countries. This differentiation has been key to the design of mechanisms to transfer between countries the technology and resources needed to mitigate emissions (including Activities Implemented Jointly, Clean Development Mechanism and Joint Implementation). Under the Kyoto Protocol and Doha Amendment, Annex I countries agreed to specific emission reduction commitments. The second commitment period (2013-2020) of the 1997 Kyoto Protocol has yet to be approved by a quorum of 144 nations. The 2015 Paris Agreement set the goal of limiting the global average temperature increase to well below 2°C above pre-industrial levels by 2100, with ambition to limit the increase to less than 1.5°C. All countries are required to present periodically to the Convention Secretariat national GHG inventories and Nationally Determined Contributions (NDCs), or emission reduction commitments. To achieve the 1.5°C goal, GHG emissions need to be decreased significantly in the coming years and be brought to net zero by around mid-century (see Chapters 21 and 22). Studies have suggested that there is a greater than 90 per cent chance of exceeding

**Table 5.2: Global environmental agreements relevant to climate change, stratospheric O<sub>3</sub> depletion and PBTs**

#### Climate change

- ❖ 1992 United Nations Framework Convention on Climate Change (UNFCCC)
- ❖ 1997 Kyoto Protocol
  - 2012 Doha Amendment
- ❖ 2016 Paris Agreement

#### Stratospheric O<sub>3</sub> depletion

- ❖ 1985 Vienna Convention for the Protection of the Ozone Layer
- ❖ 1987 Montreal Protocol on Substances that Deplete the Ozone Layer
  - 1990 London Amendment
  - 1992 Copenhagen Amendment
  - 1997 Montreal Amendment
  - 1999 Beijing Amendment
  - 2016 Kigali Amendment

#### Persistent bioaccumulative toxic chemicals (e.g. POPs and Hg)

- ❖ 1989 Basel Convention on the Control of Transboundary Movements of Hazardous Wastes and their Disposal
- ❖ 1998 Rotterdam Convention on the Prior Informed Consent Procedure for Certain Hazardous Chemicals and Pesticides in International Trade
- ❖ 2001 Stockholm Convention on Persistent Organic Pollutants
- ❖ 2013 Minamata Convention on Mercury

2°C warming under the current pledges submitted by national governments, which achieve only a third of the mitigation required to be on a least cost path to stay below that threshold. However, pathways towards staying below 1.5°C and 2°C are still technically feasible (Xu and Ramanathan 2017).

Although air pollution travels around the world, there is no single global agreement addressing air pollution; rather there is a patchwork of regional intergovernmental agreements (**Figure 5.16**). In general, this patchwork has good geographic coverage, but is uneven in terms of the coverage of pollutants, sources and capabilities. Furthermore, this patchwork does not encourage the transfer of experience and resources from richer to poorer countries. The oldest and most-developed among these is the 1979 Convention on Long-Range Transboundary Air Pollution (CLRTAP) organized under the United Nations Economic Commission for Europe (Sliggers and Kakebeeke eds. 2004; Maas and Grennfelt eds. 2016). In the Russian Federation and Central Asia, the CLRTAP overlaps with the grouping of agreements under the umbrella of the Asia and the Pacific Clean Air Partnership. There are three regional agreements on air pollution in Africa which overlap each other and have a few members in common with the Council of Arab Ministers Responsible for the Environment.

**Figure 5.16: Map of groupings of selected regional multilateral air pollution agreements**

- 1979 United Nations Economic Commission for Europe (UNECE) Convention on Long-range Transboundary Air Pollution (Geneva)
- 1998 Acid Deposition Monitoring Network in East Asia (EANET)
- 1998 Malé Declaration on Control and Prevention of Air Pollution and its likely Transboundary Effects for South Asia
- 2002 Association of Southeast Asian Nations (ASEAN) Agreement on Transboundary Haze Pollution
- 2006 Framework Convention on Environmental Protection for Sustainable Development in Central Asia (Ashkhabad)
- 2015 Asia and the Pacific Clean Air Partnership
- 2008 Eastern Africa Regional Framework Agreement on Air Pollution (Nairobi)
- 2008 Southern African Development Community Regional Policy Framework on Air Pollution (Lusaka)
- 2009 West and Central Africa Regional Framework Agreement on Air Pollution (Abidjan)
- 1986 Council of Arab Ministers Responsible for the Environment (CAMRE)
- 2008 Intergovernmental Network on Air Pollution for Latin America and the Caribbean
- No agreements

To guide their air pollution policies, many countries have developed national ambient air quality standards, or guidelines for a number of common pollutants (Kutlar Joss *et al.* 2017). These can differ with respect to the pollutant targeted, concentration level, averaging time, frequency of occurrence and measurement protocols, making comparisons of stringency difficult. In 2005, a WHO expert panel developed a set of air quality guidelines that are intended to be globally applicable for general population exposure and a set of recommended interim targets for some pollutants for areas that exceed the guidelines (WHO 2006; see **Table 5.3**). The interim targets were suggested for use by highly polluted areas as incremental steps towards achieving the guideline values. Each interim target is associated with a specified decrease in mortality risk (WHO 2006).

The ability of governments and the public to compare air quality monitoring data to such guidelines and standards and associated information about health benefits has been important in developing awareness and motivating mitigation. Thus, improving air quality monitoring infrastructure and the use of air quality and health effects information in benefit-cost analyses of mitigation measures were identified as priorities in the GEO-6 regional assessments.

Significant successes have been achieved through national and international policy and regulatory structures that have been developed over recent decades, as evidenced by the declining trends in emissions and increasing trends in activity and production (see Section 5.2). However, past policy responses may not be well suited to addressing the problems and sources

**Table 5.3: WHO Air Quality Guidelines and Interim Targets**

| Pollutant         | Averaging time | Unit              | Interim targets |     |      | Air quality |
|-------------------|----------------|-------------------|-----------------|-----|------|-------------|
|                   |                |                   | 1               | 2   | 3    |             |
| PM <sub>10</sub>  | Annual         | µg/m <sup>3</sup> | 70              | 50  | 30   | 20          |
|                   | 24 hours       | µg/m <sup>3</sup> | 150             | 100 | 75   | 50          |
| PM <sub>2.5</sub> | Annual         | µg/m <sup>3</sup> | 35              | 25  | 15   | 10          |
|                   | 24 hours       | µg/m <sup>3</sup> | 75              | 50  | 37.5 | 25          |
| NO <sub>2</sub>   | Annual         | µg/m <sup>3</sup> | –               | –   | –    | 40          |
|                   | 1 hour         | µg/m <sup>3</sup> | –               | –   | –    | 200         |
| SO <sub>2</sub>   | 24 hours       | µg/m <sup>3</sup> | 125             | 50  | –    | 20          |

### Box 5.1: UNEA 3/8 Resolution

#### Preventing and Reducing Air Pollution to Improve Air Quality Globally

The resolution urges Member States to:

- ❖ Take action to decrease all forms of air pollution
- ❖ Establish systems to monitor air quality and emissions
- ❖ Set ambitious air quality standards
- ❖ Address short lived climate pollutants as part of national action plans
- ❖ Integrate air pollution management into national development planning
- ❖ Create awareness of air pollution costs and benefits of air pollution control
- ❖ Strengthen national and sub-national capacity for air quality management

In addition, it calls for strengthened cooperation to address air pollution at the local, national, regional and global levels. The resolution also requests UN Environment to undertake additional technical support, capacity building and analysis to support Member States in improving air quality.

that remain or that are emerging, particularly in the near term. Particularly if government capacity or regulatory structures are lacking, responses that engage a broad mix of stakeholders to integrate air-related concerns into broader policy and investment decisions (e.g. transportation planning, land-use planning, economic development investments, behavioural change) may be more capable of addressing diffuse sources of emissions and promoting innovation.

Cities have been important centres of policy innovation and policy integration and continue to provide important opportunities for progress. The non-governmental organization Clean Air Asia is a leading example of efforts in this arena, bringing together city governments, national ministries, industry and other stakeholder groups from more than 1,000

cities across Asia to share lessons in developing air pollution, climate change, transportation, land-use and energy policies (Clean Air Asia 2017). The C40 Cities Climate Leadership Group is another example, which connects officials in cities to their peers in cities around the world to exchange information as they face common challenges associated with climate change mitigation and adaptation (Day *et al.* 2018).

At both international and local levels, coalitions and initiatives have formed between governments, industry and other groups to facilitate specific actions. The Climate and Clean Air Coalition for Reduction of Short-Lived Climate Pollutants (CCAC) is an example of a coordinated effort to make near-term progress focused on specific pollutants and sectors (CCAC 2015).

# Chapter 6

## Biodiversity

**Coordinating Lead Authors:** Peter Stoett (University of Ontario Institute of Technology), Jonathan Davies (University of British Columbia)

**Lead Authors:** Dolores Armenteras (Universidad Nacional de Colombia), Jeremy Hills (University of the South Pacific), Louise McRae (Zoological Society of London), Carol Zastavniuk (Golder Associates)

**Contributing Authors:** Rob Bailey (Chatham House – The Royal Institute of International Affairs), Colin Butler (University of Canberra), Irene Dankelman (Radboud University), Keisha Garcia (University of the West Indies), Linda Godfrey (Council for Scientific and Industrial Research, South Africa), Andrei Kirilenko (University of Florida), Peter Lemke (Alfred Wegener Institute), Daniela Liggett (University of Canterbury), Gavin Mudd (RMIT University), Joni Seager (Bentley University), Caradee Y. Wright (Medical Research Council of South Africa), Caroline Zickgraf (Université de Liège)

## Executive summary

Biodiversity is in crisis. There is *well-established* evidence indicating an irrevocable and continuing decline of genetic and species diversity, and degradation of ecosystems at local and global scales. Scientists are increasingly concerned that, if anthropogenic pressures on Biodiversity continue unabated, we risk precipitating a sixth mass extinction event in Earth history, with profound impacts on human health and equity. {6.1}

**Biodiversity provides many valuable goods and services – nature's contributions to people** (*well established*). Biodiversity helps regulate climate through carbon storage and control of local rainfall, filters air and water, and mitigates the impact of natural disasters such as landslides and coastal storms. Direct benefits include timber from forests, fish from oceans and freshwater systems, crops and medicines from plants, cultural identity, and the health benefits gained from access to nature. {6.1}

**Biodiversity loss has consequences for human health and equity** (*well established*). Biodiversity contributes positively to human health and well-being. The livelihoods of more than 70 per cent of the world's population living in poverty depend on natural resources to some extent and over 80 per cent of global biodiversity is found in the traditional territories of indigenous peoples. Depleting this natural capital will therefore disproportionately affect the people least able to offset losses and reduce options for future generations. {6.1}

**The loss of biodiversity reduces ecosystem resilience and increases vulnerability to threats including negative impacts of climate change** (*well established*). At local scales, it is *likely* that ecosystems with greater biodiversity are more productive and more stable through time. {6.5.4, 6.5.6}

**The critical pressures on Biodiversity are well recognized** (*well established*). Biodiversity is being eroded by land-use change, direct exploitation, climate change, pollution and invasive alien species. While habitat loss and transformation is likely the most significant present pressure, climate change may be the most significant future pressure. {6.3.1, 6.3.2, 6.3.3, 6.3.4, 6.3.5}

**Pressures often overlap and there are positive feedback loops between many of them** (*well established*). Habitat changes may increase exposure to pollutants, pests, exotic pathogens and emerging infectious diseases harmful to humans, livestock and wildlife, and exacerbate human-wildlife conflicts. Forests are experiencing alteration due to multiple land-use changes such as logging, mining, road building and agricultural expansion; the resulting habitat fragmentation and loss of biodiversity can lower forest resilience to climate change impacts and the introduction of invasive species. {6.3.1}

**Newly recognized and aggravating factors add to pressures on biodiversity** (*well established*). Energy production, resource extraction, wildlife trade and poaching, chemical waste and plastics in the marine environment are exacerbating factors that contribute to biodiversity decline. {6.3.1, 6.3.3, 6.3.4}

**Genetic diversity is the vital raw material allowing adaptation** (*well established*). The decline in the population size of many species represents a loss in genetic diversity. Genetic diversity of crops, crop wild relatives and livestock provides resilience of agricultural systems to changing environments. The ongoing long-term loss of crop and livestock genetic diversity is a threat to food security. {6.4.1}

**There is no slowing in the rate of species population decline globally** (*well established*). The increase in species extinction risks through time is *well established*, and there is no slowing in the rate of population declines globally. Freshwater species have the highest rates of population declines, whereas amphibians, reef-forming corals and cycads are the taxa with the highest proportion of species currently considered at risk of extinction. There is less data on invertebrate groups, but recent evidence indicates large declines in local abundance. The loss of invertebrate pollinators has been highlighted as a growing problem, with major consequences for agricultural production, ecosystem functioning and human well-being. {6.4.2}

**There is no global overview of ecosystem health** (*well established*). The status of many habitat types is very likely in decline. While global monitoring is challenging, across terrestrial habitats 10 out of 14 have seen a decrease in vegetation productivity, and just under half of all terrestrial ecoregions are classified as having an unfavourable status. Natural wetland areas and marine habitats, such as deep-sea ecosystems and coral reefs, are highlighted as of particular concern globally. {6.4.3}

**Biodiversity loss is being experienced across all Earth's major biomes** (*well established*). In the oceans, overexploitation of fish stocks is leading to fisheries collapse, warming is destroying coral reefs, and habitat destruction of coastal systems, such as mangrove forests, exposes communities to greater risks from erosion and extreme weather events. Marine plastic pollution is a major and growing threat to biodiversity. In freshwater systems, agricultural and chemical pollution, including increased nitrogen input, results in toxic algal blooms and a decline in drinking-water quality; invasive species are spreading through waterways; and freshwater species are declining at a faster rate than those in any other biome. In the terrestrial environment, rising temperatures are converting grasslands into deserts, and unsustainable irrigation has turned drylands into inhospitable, toxic landscapes unsuitable for wildlife or agriculture. Mountain ecosystems and polar regions are especially vulnerable to climate change, and extinctions may be likely for species at the upper limits of their thermal ranges and those dependent on sea ice. Tropical forests represent some of the most biodiverse terrestrial ecosystems, yet deforestation and forest degradation continue in many regions, often in response to demands for wood, fibre, food and fuel products such as palm oil, as well as external drivers. {6.5.1, 6.5.2, 6.5.3, 6.5.4, 6.5.5, 6.5.6, 6.5.7, 6.5.8}

**A range of national and international instruments work to conserve biodiversity** (*well established*). These include National Biodiversity Strategies and Actions Plans (NBSAPS)

under the Convention on Biological Diversity (CBD), the Strategic Plan for Biodiversity 2011-2020 (encompassing the Aichi targets), the Cartagena Protocol on Biosafety, the Nagoya Protocol, and the Intergovernmental Platform for Biodiversity and Ecosystem Services (IPBES). {6.6.1, 6.6.2}

**Species and ecosystems are most effectively safeguarded through the conservation of natural habitats** (*well established*). There has been significant progress in expanding the global network of protected areas, but the total area under protection remains insufficient, and habitats within protected areas are often degraded. {6.6.3}

**Ex-situ conservation of biological material can contribute to conserving genetic diversity** (*well established*). Seed banks and gene banks, aided by the use of these new genomic tools, have contributed to the conservation of the genetic diversity of crops and their wild relatives. Advances in technology allow cheaper and faster genome sequencing, however, genetic data for most wild species are still lacking. {6.4.1}

**At a local scale indigenous people and local communities (IPLC) play a key role in protecting biodiversity** (*well established*). IPLCs can offer bottom-up, self-driven, cost-effective and innovative solutions, and have potential to be scaled up and inform national and international practice. Such solutions provide a practical governance approach as an alternative to top-down policy-setting. This is essential to achieve many of the Sustainable Development Goals. {Box 6.6, 6.6.3}

**Biodiversity policy responses are visible and operating at international, national and local levels, but they have been insufficient to slow or reverse the decline in global biodiversity** (*well established*). There is an urgent need to bolster current policy responses. There are additional opportunities to maintain biodiversity and the contributions of nature through addressing distribution, access and governance, and by recognizing the role of IPLCs in biodiversity conservation. {6.6.3, 6.7}

**The cost of inaction is large and escalating** (*well established*). The full cost of inaction is rarely quantified; however, failure to act now will impose much higher costs in the future as shown by many examples, such as the spread of invasive species, and extinctions have immeasurable costs for future generations. {6.3.2}

## 6.1 Introduction

Biodiversity – the “variability among living organisms from all sources including ... diversity within species, between species and of ecosystems” (United Nations 1992, Article 2) – helps regulate climate through carbon sequestration and control of local rainfall, filters air and water, and mitigates the impact of natural disasters such as landslides and coastal storms. Direct benefits include food and fibres from natural vegetation, wood and non-wood products from forests, fish from oceans and freshwater systems, pollination of crops, medicines from plants, and psychological health (Clark *et al.* 2014; Harrison *et al.* 2014; World Health Organization [WHO] and Secretariat of the Convention on Biological Diversity [SCBD] 2015, p. 200; Pascual *et al.* 2017). Never before have we known so much about the biodiversity that enables ecosystems to function (Cardinale *et al.* 2012), yet biodiversity loss and habitat decline continues to accelerate, potentially beyond planetary boundaries (Tittensor *et al.* 2014; Steffen *et al.* 2015).

Current rates of species loss are estimated to be 1,000-fold greater than background rates (Pimm *et al.* 2014), sparking debate among scientists over whether we have already entered into a sixth mass extinction event (Barnosky *et al.* 2011; Ceballos, Ehrlich and Dirzo 2017). For many species, populations are in decline globally (Ceballos, Ehrlich and Dirzo 2017; McRae, Deinet and Freeman 2017), and genetic diversity – vital for future adaptation to global change – is eroding (Food and Agriculture Organization of the United Nations [FAO] 2015a). Natural communities of plants and animals are being reshaped through climate change and human-mediated movement of species (Pacifi *et al.* 2015); some displaced species are invasive, posing risks to human health, genetic diversity, and food and water security. These changes seem likely to reduce the efficiency by which ecosystems are able to capture essential resources, produce biomass, decompose and recycle nutrients (Cardinale *et al.* 2012), and decrease the resilience of ecosystems (MacDougall *et al.* 2013). The restoration and maintenance of biodiversity will enhance

**Figure 6.1: Schematic from the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services describing the main elements and relationships linking nature, biodiversity and ecosystem services, human well-being and sustainable development. (In this diagram, anthropogenic drivers equate to the pressures as described in Section 6.3)**

Source: IPBES (2013, p. 2).

adaptive potential, and help sustain nature's contributions to people's livelihoods, health and well-being (Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services [IPBES] 2016). These critical services are frequently neglected as they largely bypass the market and there are no clear price signals for them (e.g. Foale *et al.* 2013; Seddon *et al.* 2016; Costanza *et al.* 2017). The loss of biodiversity is also a significant equity issue: the livelihoods of 70 per cent of people living in poverty rely to some extent on natural resources (Green Economy Coalition 2012, p. 4); 80 per cent of global biodiversity is found in the traditional territories of indigenous peoples (Sobrevila 2008, p. xii); and future generations will experience relatively impoverished lives if losses continue (Naeem *et al.* 2016).

## 6.2 Further assessments since the fifth Global Environmental Outlook (GEO-5)

GEO-5 (United Nations Environment Programme [UNEP] 2012) concluded that pressure on biodiversity continues to increase through habitat loss, degradation from agriculture and infrastructure development, overexploitation, pollution, invasive alien species and climate disruption, as well as interactions between these pressures, and that the state of global biodiversity is continuing to decline with substantial ongoing losses of populations, species and habitats. Since GEO-5, a midterm assessment of progress towards the Aichi Biodiversity Targets concluded that while progress has been made, this was insufficient to achieve them by 2020 (SCBD 2014). A series of GEO regional assessments (UNEP 2016a; UNEP 2016b; UNEP 2016c; UNEP 2016d; UNEP 2016e; UNEP 2016f), State of Biodiversity reports looking at regional progress towards the Aichi Biodiversity Targets (United Nations Environment Programme World Conservation Monitoring Centre [UNEP-WCMC] 2016a; UNEP-WCMC 2016b; UNEP-WCMC 2016c; UNEP-WCMC 2016d), and regional assessments on biodiversity and ecosystem services from the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES) (<https://www.ipbes.net/outcomes>), have summarized evidence for declines in the state of biodiversity from different parts of the world while highlighting variation in responses to regional pressures. Among many other developments encouraged by

these assessments, the gradual acceptance of the numerous benefits of biodiversity conservation for human health has been recognized (WHO and SCBD, 2015; see also **Box 6.1**).

### Box 6.1: Biodiversity, disease and One Health

Several dimensions of global change, including shifts in urbanization, agricultural practices, land use and biodiversity, are altering ecological dynamics and in some cases facilitating human-animal contact that exacerbates the risk of zoonotic disease emergence and spread. Zoonotic diseases are transmissible from domestic or wild animals to humans through direct contact or through water, food and the environment (WHO and SCBD 2015; Centers for Disease Control and Prevention [CDC] 2017).

One Health is an approach that recognizes the opportunities and challenges related to these interconnections at the human-animal-ecosystem interface, and aims for optimal health outcomes for all; it is particularly relevant in the prevention and control of zoonoses, which account for more than 60 per cent of human infectious diseases (Karesh *et al.* 2012; WHO and SCBD 2015; CDC 2017).

The United States Agency for International Development (USAID) Emerging Pandemic Threats PREDICT project is expanding the detection and discovery of zoonotic viruses with pandemic potential through surveillance in 'hotspots' for emerging infectious diseases (EIDs), such as Ebola, to help track their circulation and understand factors driving their emergence (Kelly *et al.* 2017; Marlow 2017). Using the One Health approach, the project considers the behaviours, practices, and ecological and biological factors driving disease emergence, transmission and spread. Through enhanced understanding of EID risks, countries can be better equipped to prevent, prepare for and respond to the threat of an outbreak, ideally through taking preventive measures before major disease outbreaks. PREDICT partners include the University of California Davis One Health Institute, USAID, EcoHealth Alliance, Metabiota, Wildlife Conservation Society, and Smithsonian Institution.

### 6.3 Drivers

Drivers of environmental change – population demography, urbanization, economic development, technology and innovation, and climate change (see Chapter 2) – impose multiple negative impacts on biodiversity, leading to loss of genetic diversity, population declines that have pushed some species towards a heightened risk of extinction, and the reshaping of natural communities, with ramifications for the stability and functioning of ecosystems (Figure 6.2). While most drivers are projected to increase, climate change is likely to become the dominant driver of biodiversity change in the next few decades (Leadley *et al.* 2014; Newbold *et al.* 2015). Ultimately, reducing pressures on biodiversity will require addressing these drivers of change.

### 6.4 Pressures

The main direct pressures on global biodiversity are habitat stress and land-use change, invasive species, pollution, unsustainable use/overexploitation and climate change (mainly as a consequence of higher temperatures, changes in precipitation patterns and increasing frequency and severity of extreme weather events and wildfires) (UNEP 2012). The spatial distribution and combination of these pressures varies across the globe (Figure 6.3) and affects species groups in different ways (Figure 6.4), although detailed data for invertebrates, which comprise most of the diversity of life, are lacking (Collen *et al.* 2012).

**Figure 6.2: Interconnections between people, biodiversity, ecosystem health and provision of ecosystem services showing drivers and pressures**

#### 6.4.1 Land-use change and habitat loss

The global human footprint – infrastructure, land cover and human access into natural areas – is expanding (Figure 6.5) (Venter *et al.* 2016). Economic drivers and demographic pressures are the primary sources of accelerating land-use change. These drive agricultural expansion – the largest contributor to land-use change – for food, commodities, fodder and biofuels (Alexander *et al.* 2015), demand for extraction of mineral, metal and energy resources (Mudd and Jowitt 2017), urbanization, road building, land-take and deforestation, land degradation, desertification and habitat fragmentation.

Urban growth is a major driver of land-use change and habitat loss through deforestation. In developing countries, the establishment and expansion of urban areas (many of which lack adequate planning) and the growth of infrastructure can coincide with biodiversity hotspots (UNEP 2016d). Road construction facilitates the spread of invasive species, and allows for easier access into previously intact habitats, exposing them to threats from hunting and resource exploitation (Alamgir *et al.* 2017). Additional land-use practices, such as burning (or the suppression of natural fire) (Smith *et al.* 2016) and livestock grazing, impose further pressures on already degraded systems (Royal Botanic Gardens Kew 2010). The marine environment is equally affected and heavily impacted by commercial fishing practices, such as bottom trawling, coastal development and dredging (Ocean Health Index 2017) (see Chapter 7). International trade can export threats to biodiversity, resulting from demand in developed countries, to developing countries (Lenzen *et al.* 2012). Many of the causes of habitat destruction also contribute to human population pressure and movement, which further compound threats to biodiversity (Black *et al.* 2011) (see Chapter 2).

Pressure from agricultural land use is widely expected to increase (Kehoe *et al.* 2017). Global food production is forecast to rise by between 60 and 100 per cent by 2050 as a result of population growth and economic development, with an accompanying minimum net increase in land under crop production of 70 million ha (Tilman *et al.* 2011; Alexandratos and Bruinsma 2012) (see Chapter 8). Large-scale industrial agriculture has many unfavourable environmental and social effects, such as land degradation, albedo changes, increase in methane emissions and loss of carbon sequestration capacities (Laurance, Sayer and Cassman 2014; Dangal *et al.* 2017; Houspanossian *et al.* 2017). Agricultural intensification can reduce pressure on non-agricultural lands (Phalan *et al.* 2016), but may have detrimental impacts on wild plant and animal species that cohabit within diverse agroecosystems (Emmerson *et al.* 2016).

Rapid development-induced impacts result from the construction of dams, mines and other hard infrastructure developments, including those associated with energy production (Butt *et al.* 2013).

Climate warming and increasing frequency of extreme weather events contribute to habitat loss and degradation (see Chapter 2). Warming seas are reducing sea ice extent (critical hunting habitat for polar bears, seals and fishing birds) (Intergovernmental Panel on Climate Change [IPCC] 2014, p. 80) and, in conjunction with elevated atmospheric CO<sub>2</sub>, acidifying ocean habitats (Hoegh-Guldberg *et al.* 2017). Extreme weather events, such as flooding, drought and fire, can accelerate the degradation of already vulnerable habitats (IPCC 2014, p. 294).

Land-use change, which may impact both aquatic and terrestrial environments, can result in:

- ❖ exposure to pollutants, exotic pathogens and emerging infectious diseases harmful to humans, livestock and wildlife (WHO and SCBD 2015, pp. 1-19);
- ❖ increased human conflict (Ghazi, Muniruzzaman and Singh 2016, p. ii);
- ❖ loss of habitat for wild species and the ecosystem services they provide, such as pollinators and predators of agricultural pests (Potts *et al.* 2016; Woodcock *et al.* 2016); and
- ❖ loss of human access to nature (see Chapter 8), with disproportionate impacts on vulnerable and indigenous communities (Haines-Young and Potschin 2010).

**Figure 6.5: Map of the global human footprint for 2009 (combined pressures of infrastructure, land cover and human access into natural areas, using a 0-50 on a cool to hot colour scales) (a), and absolute change in average human footprint from 1993 to 2009 at the ecoregion scale (b)**

Source: Venter *et al.* (2016).

## 6.4.2 Invasive species

Invasive species threaten ecosystems, habitats and other species (Bellard, Cassey and Blackburn 2016). They are usually non-native (invasive alien species) but can also include expanding native populations (Nackley *et al.* 2017). The annual rate of first records of non-native species has increased during the last 200 years and the increase in numbers does not show any sign of saturation, meaning that efforts to mitigate invasions have not been effective (Seebens *et al.* 2017). The ecological impacts of invasive species are felt through direct and indirect competition, predation, habitat degradation, hybridization, and their role as disease agents and vectors – also a threat to human health and food security (Figure 6.6) (Strayer 2010; Paini *et al.* 2016).

**Figure 6.6: Impact mechanism of invasive alien species on threatened species in Europe**

Source: Genovesi, Carnevali and Scalera (2015).

Invasive plants can impact the provisioning of key ecosystem services, such as access to clean water, by the congestion and eutrophication of waterways, degradation of catchment areas, and viability of pasture and rangeland (Packer *et al.* 2017). Invertebrate species that have become invasive may pose an even greater risk. The population expansion of the invasive zebra mussel in the North American Great Lakes was so great that it impeded water flow of municipal water supplies and hydroelectric companies (Rapai 2016). Invasive pests, such as the gypsy moth, emerald ash borer and hemlock woolly adelgid in North America, have both large biodiversity and economic impacts (Aukema *et al.* 2011). Invasive insect vectors can also facilitate the spread of parasites and emerging infectious diseases (Rabitsch, Essl and Schindler 2017), including chikungunya, dengue and Zika, which are vectored by

mosquitoes (Akiner *et al.* 2016). Invasive vertebrates present grave danger on islands (Spatz *et al.* 2017), where they may be the major driver of biodiversity loss (Leadley *et al.* 2014; Doherty *et al.* 2016).

The economic costs, both direct and indirect (e.g. costs of control efforts), amount to many billions of dollars annually (for regional estimates see Kettunen *et al.* 2008; Pejchar and Mooney 2009; van Wilgen *et al.* 2012). The cost of restoring lost ecosystem services following invasion of the Laurentian Great Lakes by the spiny water flea was estimated to be between US\$86.5 million and US\$163 million (Walsh, Carpenter and Vander Zanden 2016). These costs do not reflect the additional environmental and societal/cultural impacts of invasive species.

Major routes for species invasion include deliberate release, escape and accidental introductions via trade, tourism and ship ballast water (CBD 2014; Early *et al.* 2016). Good governance may decrease invasion risk from trade (Brenton-Rule, Barbieri and Lester 2016), whereas climate change may facilitate increased spread by opening up new niche space (Wolkovich *et al.* 2013) and lowering barriers to establishment, especially in more extreme environments (Duffy *et al.* 2017). Loss of native biodiversity is likely to enhance invasion risk, while rising temperatures in cold regions increase the likelihood of establishment (Molina-Montenegro *et al.* 2012; Cuba-Díaz *et al.* 2013; Chown *et al.* 2017). Future threats are posed by increased transport in the Arctic with the decrease in sea ice, commercial use of microbes in crop production, horizontal gene transfer from genetically modified organisms, and the emergence of invasive microbial pathogens (Ricciardi *et al.* 2017).

## 6.4.3 Pollution

Pollution can take many forms (e.g. waste and chemical products deliberately or accidentally released into the environment, but also light, noise, heat and microbes); major emitters include transport, industry, agriculture (Landrigan *et al.* 2017) and aquaculture (Klinger and Naylor 2012; Bouwman *et al.* 2013). Emerging pollutants include a wide range of synthetic chemicals, pesticides, cosmetics, personal and household care products, and pharmaceuticals (Gavrilescu *et al.* 2015; Landrigan *et al.* 2017).

On land, open waste dumps have local impacts on plants and animals (see Chapter 8), and soil pollution can affect the microbial population and reduce important ecosystem functioning (Wall, Nielson and Six 2015). Pesticides, fertilizers and other chemicals used in agricultural processes can harm pollinators and natural predators of pests (Woodcock *et al.* 2016), with surface run-off also impacting freshwater and coastal biodiversity (see Chapters 7 and 9). Bioaccumulation of toxins, including heavy metals (Araújo and Cedeño-Macias 2016), may have cascading impacts across the entire food chain, including humans. In marine and freshwater environments, the accumulation of microplastic and nanoplastic pollution (see Chapter 7 and Box 6.2) has been identified as an emerging issue (SCBD 2016).

The accumulation of endocrine-disrupting chemicals (EDCs) and persistent organic pollutants (POPs) in natural ecosystems pose additional threats to wildlife (Bergman *et al.* eds. 2013), particularly in aquatic systems (Wang and Zhou 2013) (see Chapter 9).

## Box 6.2: The threats to biodiversity from marine litter and microplastics

Marine litter, including marine plastic litter and microplastics, is considered a major threat to biodiversity, with serious impacts reported over the last four decades (SCBD 2012). Recent research shows that more than 800 marine and coastal species are now affected through ingestion, entanglement, ghost fishing or dispersal by rafting (SCBD 2016). Between 2012 and 2016, aquatic mammal and seabird species known to be affected by marine litter ingestion increased from 26 per cent and 38 per cent to 40 per cent and 44 per cent, respectively (SCBD 2016). Plastics, which constitute 75 per cent of marine litter, have been shown to act as carriers for persistent bioaccumulative and toxic substances (PBTs); provide habitats for unique microbial communities; act as a potential vector for disease; and provide a means to transport invasive alien species across oceans and lakes (Rochman *et al.* 2013; SCBD 2016). Research on the physical and toxicological effects of microplastic provides evidence of trophic transfer in planktonic food chains as well as the direct uptake of microplastics by marine invertebrates (Wright, Thompson and Galloway 2013; SCBD 2016). Ingestion of microplastic by fish has been shown to cause physiological stress, liver cancer and endocrine dysfunction, affecting female fertility and the growth of reproductive tissue in male fish (Joint Group of Experts on the Scientific Aspects of Marine Environmental Protection [GESAMP] 2015). According to the United Nations, 51 trillion microplastic particles, 500 times more than stars in our galaxy, litter our seas, seriously threatening marine wildlife (van Sebille *et al.* 2015).

Air pollution contributes to the acidification and eutrophication of terrestrial ecosystems, lakes, estuaries and coastal waters (O'Dea *et al.* 2017; Payne *et al.* 2017), and to mercury bioaccumulation in aquatic food webs (Lavoie *et al.* 2013) (see Chapter 5).

### 6.4.4 Overexploitation

Overexploitation includes illegal, unreported and unregulated fishing, illegal and unsustainable logging, overgrazing, unregulated bushmeat consumption, wildlife poaching and illegal killing (often for foreign markets). It also includes legal but ecologically unsustainable harvesting as a consequence of poorly designed quotas, lack of knowledge of the resource base or new advances in technology that allow more efficient resource exploitation. Direct exploitation has resulted in threats to iconic land and marine species alike, such as the beluga sturgeon prized for caviar (He *et al.* 2017), sharks harvested for their fins (Worm *et al.* 2013), rhinoceros species targeted by poachers for their horns (Figure 6.7), African elephants hunted

for their ivory (Maxwell *et al.* 2016), the Andean condor of South America hunted for feathers and bones (Williams *et al.* 2011), and agarwood (*Thymelaeaceae*) harvested for perfume and incense (United Nations Office on Drugs and Crime [UNODC] 2016, p. 59).

Illegal trade in wildlife, fisheries and forest products is extensive, with estimates of their combined value between US\$90- 270 billion per year, and links to transnational organized crime (UNEP 2014; Stimson Center 2016; Stoett 2018; see also 'Project Predator' case study in Section 13.3.2). Poverty provides a strong incentive for poaching, while economic development can improve infrastructure that facilitates access to wildlife-rich areas and fuels demand for wildlife products (UNODC 2016, p. 19). However, legal but unsustainable exploitation of wildlife is likely an even greater threat to biodiversity than currently illegal practices (FAO 2018a). The impact of mismanaged harvesting is perhaps most clearly evident in marine fisheries (see Section 6.6.1, and Chapter 7), although future projections are less certain (Costello *et al.* 2016).

**Figure 6.7: Recorded number of rhinoceros poached in South Africa, 2007-2015. In 2011, the rhino population in South Africa numbered just over 20,000**

Source: South Africa Department of Environmental Affairs (2016).

The overexploitation of wildlife has implications for equity as it deprives poor and vulnerable local communities and indigenous peoples of sustenance, traditional medicines, tourist income and other ecosystem benefits (Haines-Young and Potschin 2010; O'Neill *et al.* 2017). Conversely, increased regulation of wildlife harvesting can have positive societal consequences, such as strengthening women's leadership roles, which may feed back into biodiversity conservation policy designs (FAO 2016).

#### 6.4.5 Climatic warming and extreme events

The impacts of anthropogenic climate change on biodiversity are most evident in natural systems (IPCC 2014, p. 40), and manifest as changes in both average climate and frequency of extreme weather events (see Box 6.3). One estimate suggests that up to one in six species could be threatened with extinction by 2050 if current warming trends continue (Urban 2015). However, known impacts are not distributed evenly and our knowledge of impacts remains incomplete (Figure 6.8).

In response to rising temperatures, species may move to cooler locations or alter their phenology to flower, breed or migrate sooner (Parmesan 2006; Scheffers *et al.* 2016). Evidence suggests they are doing both: species are moving, on average, 16.9 km per decade to higher latitudes or 11 m per decade upward in elevation (Chen *et al.* 2011), and advances in flowering phenology are suggested to be between 2.3 and 5.1 days per decade (Wolkovich *et al.* 2012; IPCC 2014). There is increasing speculation that such climate-induced shifts in distributions and phenologies might cascade through trophic interactions, resulting in species asynchronies, such as between flowers and their pollinators. An analysis of over 10,000 time series suggests climate sensitivity (i.e. phenological shift in response to climate change) differs among trophic groups (Thackeray *et al.* 2016), but data on interacting species remains sparse (Kharouba *et al.* 2018).

#### Box 6.3: Extreme events – further pressures on biodiversity

Natural disasters, such as earthquakes and tsunamis, or floods, landslides, wildfires and droughts following extreme weather events kill and injure hundreds of thousands of people a year, cause widespread destruction to ecological habitats, and threaten wildlife populations with local extinction. Following the 2011 Great East Japan earthquake and tsunami, there was an overall decline in local species diversity, and coastal forests and other vegetation on sandy beaches and low-lying coastal areas were severely damaged (Miura, Sasaki and Chiba 2012; Hara *et al.* 2016). The loss of natural coastal habitat, such as mangrove forest and coral reefs, through pollution, habitat transformation and increased sea surface temperatures, can further undermine protection of coastlines from waves, storm surges and coastal erosion. When communities are rapidly rebuilt post-disaster, building material is often gathered unsustainably, posing an additional threat to local habitats, and communities can be relocated to environmentally sensitive areas.

In the marine environment, warming and acidifying oceans are associated with coral bleaching events, with unprecedented pan-tropical bleaching recorded during 2015-2016 (Hughes *et al.* 2017) (see Section 7.3.1). Ocean acidification may also have negative impacts on other marine systems, including mussel beds and some macroalgal habitats (Sunday *et al.* 2017). Warmer waters additionally impose direct metabolic costs on reef fish, reducing swimming capacity and increasing mortality rates (Johansen and Jones 2011). In polar regions, decrease in sea ice and greater surface run-off may increase primary and secondary productivity, altering food-web dynamics (Post *et al.* 2013), and increase the probability of the establishment of invasive species (Duffy *et al.* 2017) (see Section 4.4.2).

Source: Pacifici *et al.* (2015).

## 6.5 Global state and trends of biodiversity

Global change is having negative impacts across all dimensions of biodiversity, from genes to ecosystems. However, the genetic diversity of most natural populations remains unmeasured, population baseline data is often lacking, and the status of ecosystems is under evaluated. More data and science-based targets for evaluation are needed urgently.

### 6.5.1 State and trends in genetic diversity

Genetic diversity is of fundamental importance not only as the raw material for continued adaptation of wild species by natural selection, but also in maintaining and enhancing the diversity of cultivated plants and breeds of livestock underpinning the resilience of agricultural systems and food security (Khoury *et al.* 2014; FAO 2015a; Bruford *et al.* 2017). Conservation of genetic diversity can be implemented *in situ* in the wild or crop fields, or increasingly *ex situ* in gene banks and seed collections maintained at local and national levels (see Section 13.2.4).

Long-term declines in the number of varieties of crops and breeds of livestock continue, and much of this diversity, alongside that of wild relatives and lesser used species, still lacks sufficient protection (FAO 2015a). More than 35 species of birds and mammals have been domesticated for use in agriculture and food production, and there are about 8,800 recognized breeds (FAO 2018a). An assessment of extinction risk for existing local animal breeds found 65 per cent are classified as 'status unknown' because of missing population data or lack of recent updates, 20 per cent as 'at risk' and only 16 per cent as 'not at risk' (FAO 2018a). These proportions vary regionally, particularly with respect to the availability of data (Figure 6.9).

**Figure 6.9: Proportions of local animal breeds, classified as being at risk, not at risk or unknown level of risk of extinction**

Source: FAO (2018a).

New genomic tools that allow rapid and increasingly low-cost DNA sequencing have become an integral part of conserving genetic diversity *ex situ*, helping us to understand the genetic potential of crop wild relatives for enhancing productivity, nutritional content and resilience to environmental change (Royal Botanic Gardens Kew 2016). As of 2017, some 225 species of plants, mostly crops, had complete genome sequences (Royal Botanic Gardens Kew 2017; see **Figure 6.10**). However, this remains an expensive enterprise and there is an ongoing need to share related information with those whose livelihoods are dependent on biodiversity but lack the resources to access such data.

Traditional approaches to breeding-enhanced varieties of plants and breeds of livestock still predominate; however, genetically modified (GM) organisms continue to draw attention and new advances, such as the CRISPR/Cas genome editing techniques, are advancing synthetic biology (SCBD 2015; CBD 2016). There is evidence of the positive contribution of genome-editing techniques through the control of invasive species (Webber, Raghu and Edwards 2015) due to the lessened need for insecticides that are harmful to non-target organisms (e.g. Li *et al.* 2015). However, the propagation of genome-edited crops may also contribute to negative biodiversity and environmental outcomes, such as facilitating the spread of herbicide-resistant weeds (Rótolo *et al.* 2015) and reduced insect diversity (Schütte *et al.* 2017; Tsatsakis *et al.* 2017), and the natural adaptation of ecosystems to GM traits may ultimately require further technological innovation and increased use of herbicides and insecticides (Rótolo *et al.* 2015).

The conservation status of genetic diversity for most wild species unrelated to agricultural crops and livestock remains poorly documented (although there are concerted efforts

to close this gap, see <http://www.genomicobservatories.org/>). Yet population declines are increasingly commonplace (Ceballos, Ehrlich and Dirzo 2017; McRae, Deinet and Freeman 2017). A loss in population size, particularly when persisting over several generations, frequently translates into a loss in genetic diversity. Thus, the drivers that threaten species and populations also likely erode the genetic diversity within them.

### 6.5.2 Global state and trends in species

The global decline in biodiversity as illustrated by trends in species remains striking (Dirzo *et al.* 2014). Many observers have suggested that we are witnessing a new mass extinction event (Ceballos *et al.* 2015), although there is as yet no scientific consensus. The International Union for the Conservation of Nature's (IUCN) (**Box 6.4**) Red List of Threatened Species (<http://www.iucnredlist.org/>) provides the most comprehensive inventory of the global conservation status of plant, animal and fungi species. The status of vertebrates has been relatively well studied (Rodrigues *et al.* 2014), but fewer than 1 per cent of described invertebrates (Collen *et al.* 2012) and only about 5 per cent of vascular plants (Royal Botanic Gardens Kew 2016) have been assessed for extinction risk.

According to IUCN's latest estimates, cycad species face the greatest risk of extinction with 63 per cent of species in this plant group considered threatened (**Figure 6.11**). The most threatened group of vertebrates are amphibians (41 per cent). Of the few invertebrate species assessments completed, 42 per cent of terrestrial, 34 per cent of freshwater and 25 per cent of marine species are considered at risk of extinction (Collen *et al.* 2012). Among well sampled invertebrate groups, reef-forming corals have the highest proportion (33 per cent) of species under threat.

**Figure 6.10: Cumulative number of species with whole genome sequences (2000-2016)**

Colours denote the type of species: crops, usually for food; crop wild relatives; model species to help understand plant ecology or evolution; other species, e.g. dominant species in an ecosystem.

Source: Royal Botanic Gardens Kew (2017).

**Figure 6.11: The proportion of species in each extinction risk category of the IUCN Red List of Threatened Species**

The numbers to the right of each bar represent the total number of existing species assessed for each group. EW: Extinct in the wild; CR: Critically endangered; EN: Endangered; VU: Vulnerable; NT: Near threatened; DD: Data deficient; LC: Least concern.

#### Box 6.4: International Union for the Conservation of Nature (IUCN)

The International Union for Conservation of Nature (IUCN) has, since 1948, served as a science-policy interface for biodiversity and ecosystem services. IUCN has a membership of which the governance weight is exactly 50 per cent intergovernmental (with over 200 state and government agency members) and exactly 50 per cent civil society and indigenous peoples' organizations (over 1,000 civil society members). The Union mobilizes independent commissions to provide expert input into pressing challenges of nature conservation; there are currently six commissions (Ecosystem Management, Education and Communication, Environmental Economic and Social Policy, Species Survival Commission, World Commission on Environmental Law, and World Commission on Protected Areas), comprising over 10,000 specialists in total. The IUCN Red List of Threatened Species, initiated in 1964, remains the most authoritative global inventory of endangered species today (Figure 6.11).

For those groups that have been comprehensively assessed more than once, changes in extinction risk through time have been examined using the IUCN Red List Index. The evidence suggests an increase in risk of extinction for all groups individually and as an aggregate from 1993 to 2017 (Figure 6.12).

**Figure 6.12: Red List Index of species survival for birds, mammals, amphibians, corals and cycads, and an aggregate (in light green) for all species**

A decline in the trend line indicates either more species have become at risk of extinction over time or there has been an increase in the level of extinction risk over time for some species. The shading denotes 95 per cent confidence intervals.

Sources: IUCN (2017a), Hoffman *et al.* (2018).

**Figure 6.13: Global Living Planet Index**

The centre line shows the index values indicating a 60 per cent decline between 1970 and 2014 and the upper and lower lines represent the 95 per cent confidence limits surrounding the trend. This is the average change in population size of 4,005 vertebrate species, based on data from 16,704 time series from terrestrial, freshwater and marine habitats.

Source: WWF (2018).

Monitoring the abundance of species provides a complementary indicator of status and trends. Although lacking the comprehensive coverage of many taxonomic groups found in the IUCN Red List Index, these indicators provide finer spatial and temporal resolution. Trends in global vertebrate species population abundances as measured by the Living Planet Index (Figure 6.13) show an average decline of 60 per cent between 1970 and 2014 (McRae, Deinet and Freeman 2017; WWF 2018). Freshwater species have higher rates of population declines than either terrestrial or marine species (McRae, Deinet and Freeman 2017). Globally, average local abundance of terrestrial species is estimated to have fallen to 85 per cent of modelled abundances in the absence of

anthropogenic land-use change (Newbold *et al.* 2016), although the intactness of biodiversity varies spatially (Newbold *et al.* 2015; Newbold *et al.* 2016; Figure 6.14), and data on species population trends of both flora and fauna are sparse.

Trends in invertebrates may well echo those observed in vertebrates. A global index sampling populations of 452 invertebrate species revealed an average 45 per cent decline in abundance over 40 years (Dirzo *et al.* 2014) and recent reports of declines greater than 75 per cent in biomass of flying insects has been found in protected areas in Germany (Hallmann *et al.* 2017), with similar findings emerging elsewhere in Western Europe (Vogel 2017) and central Europe (Hussain *et al.* 2017;

**Figure 6.14: Terrestrial Biodiversity Intactness Index**

Intactness value is the average abundance of species as a percentage of the modelled abundance in an undisturbed habitat.

Source: Newbold *et al.* (2016).

Hussain *et al.* 2018). Particularly steep declines were observed in hoverflies, which are important pollinators (Vogel 2017). Declines in pollinator abundance have also been documented elsewhere, for example, bumble bee species in North America (Bartomeus *et al.* 2013).

The Living Planet Index (Figure 6.13) and the Biodiversity Intactness Index (Figure 6.14) both indicate that terrestrial species abundance has declined as a result of anthropogenic land-use change, and that the trend of population decline in the last 44 years has shown no sign of slowing (McRae, Deinet and Freeman 2017; WWF 2018). It has been suggested from the Biodiversity Intactness Index that a terrestrial planetary boundary has been crossed (based on a reduction of 10 per cent in Biodiversity Intactness); from this, it is inferred that ecosystem function may be impaired (Newbold *et al.* 2016).

### 6.5.3 Global state and trends in ecosystems

There is a pressing need to expand ecosystem assessments. The IUCN has begun to issue a Red List for Ecosystems to complement its global species-based assessment (Keith *et al.* 2015), and a few ecosystems have been assessed by global and regional criteria. One ecosystem, the Aral Sea, has been assessed as 'collapsed' (Figure 6.15) (Sehring and Diebold 2012; Keith *et al.* 2013), and several others, such as the gnarled mossy cloud forest on Lord Howe Island of Australia, and the Gonakier forests of the Senegal river floodplain shared by Senegal and Mauritania, have been listed as 'critically endangered' (see Red List of Ecosystems; IUCN 2017b).

Collapse may be reversible if all the component parts of the collapsed ecosystem still exist in other ecosystems (Rodríguez

**Figure 6.15: Mechanisms of ecosystem collapse, and symptoms of the risk of collapse**

Source: Keith *et al.* (2013).

*et al.* 2015). However, shifts to alternative stable states, such as that documented in coral reef systems, from coral dominated to algal dominated, with human-induced eutrophication, cannot be simply reversed (Hughes *et al.* 2017).

**Figure 6.16: Mean percentage change in each broad habitat type based on satellite imagery: (a) change from original land-cover type between 2001 and 2012; (b) vegetation productivity as measured using the Enhanced Vegetation Index between the years 2000-2004 and 2009-2013**

Source: Royal Botanical Gardens Kew (2016).

Some information is available at a large scale for broad terrestrial habitat types, and it is estimated that 10 out of 14 experienced a decrease in vegetation productivity between 2000 and 2013, while 4 increased in productivity (**Figure 6.16**), with anthropogenic factors thought to be driving these trends (Royal Botanical Gardens Kew 2016). At a finer scale, 24 per cent of terrestrial ecoregions have been classified as 'Nature imperilled' (Dinerstein *et al.* 2017).

More is known about the status of terrestrial species and ecosystems than their aquatic counterparts. However, an average decline in natural wetland area of about 30 per cent between 1970 and 2008 was observed globally (Dixon *et al.* 2016), varying from a 50 per cent decline in Europe to 17 per cent in Oceania. While the spatial extent of anthropogenic impacts on marine ecosystems has been estimated (Jones *et al.* 2018), relatively little is known about their current status. Nonetheless, the impact of pressures on the marine environment is thought to be increasing, as evidenced by marine wildlife loss (McCauley *et al.* 2015) and the current critical status of coral reefs (Hughes *et al.* 2017). The deep-sea ecosystem is probably one of the least well studied and is expected to be particularly vulnerable to habitat loss and climate change (Barbier *et al.* 2014).

The status of biodiversity that explicitly underpins nature's contribution to people has not yet been comprehensively assessed, although a global assessment of biodiversity and ecosystem services will be published by IPBES in 2019. However, many of these ecosystem processes are thought to be under threat as a consequence of observed wildlife declines and ongoing threats to biodiversity (Cardinale *et al.* 2012; Mace, Norris and Fitter 2012). Mammal and bird species that are used for food and/or medicine are at greater risk of extinction than those not used; the opposite was found for the same assessment of amphibian species (Almond *et al.* 2013). The perceived value of a species may impose an additional pressure on biodiversity conservation: of the 28,187 plant species that are recorded as being of medicinal use, there are controls on international trade for 1,280 to reduce threats from overexploitation (Royal Botanical Gardens Kew 2017).

## 6.6 Impacts on the world's biomes

A biome is defined as a major ecological community of organisms adapted to a particular climatic or environmental condition across a large geographic area. Within biomes, several ecosystems may coexist. This section examines eight broadly defined biomes that encompass most of Earth's biodiversity.

### 6.6.1 Oceans and coasts

The primary pressures on open ocean biodiversity are overexploitation, pollution from land-based activities and climate change; coastal ecosystems have additional pressures associated with habitat destruction, aquaculture and invasive species (see Section 7.2). Although data are limited, these pressures affect the state of marine biodiversity from populations to ecosystems.

Coastal systems are particularly vulnerable; for example, between 20 and 35 per cent of mangrove area has been lost since 1980 (Innis and Simcock eds. 2016) and the current annual rate of seagrass habitat destruction is about 8 per cent (Innis and Simcock eds. 2016). Coral reefs are among the most biodiverse marine ecosystems, yet they are also among the most fragile (see Section 7.3.1).

The decline in the health of marine ecosystems and biodiversity is increasingly affecting people (WWF 2015). Marine capture fisheries provide healthy food and support livelihoods (see Section 7.3.2). However, overexploitation is leading to population declines in marine fisheries with the percentage of global stocks fished at biologically unsustainable levels increasing from 10 per cent in 1975 to 33 per cent in 2015, with the largest increases in the late 1970s and 1980s (FAO 2018b; **Figure 6.17**). In 2015, over 50 per cent of the stocks in the Mediterranean, Black Sea, the Pacific Southwest and the Atlantic Southwest were fished at biologically unsustainable levels (FAO 2018b).

Exploitation of target species is coupled with additional negative biodiversity impacts from by-catch and damage to benthic environments from trawling, although some seabird populations have increased through feeding on discards (Foster, Swann and Furness 2017). The rise of aquaculture can reduce pressures of exploitation for some wild species, but can also lead to invasive species, inter-species breeding, eutrophication and disease spread (Ottinger, Clauss and Kuenzer 2016) (see Section 7.4.3).

Pollution, including marine plastic litter and microplastics (see **Box 6.2**), and loss and degradation of habitat leads to further reduced contributions from natural systems, such as declining fish nursery grounds or mangrove wood supply (Nordlund *et al.* 2016; Quinn *et al.* 2017), as well as increases in vulnerability to extreme events (see **Box 6.3**) through reduced coastal protection.

### 6.6.2 Freshwater

Freshwater systems are exposed to the full gamut of multiple pressures with changes in land use, habitat loss, invasive species, use of watercourses for development of hydroelectric power, and pollution creating widespread and significant impacts (see Section 9.2). Wetland loss has been long term and extensive, and freshwater species, especially in tropical ecosystems, have declined at a faster rate than those in any other biome (see Section 6.4.1).

**Figure 6.17: Global trends in the state of the world's marine stocks 1975-2015**

Source: FAO (2018b).

The abundance of monitored populations of freshwater vertebrate species declined an average of 81 per cent over the past 42 years (WWF 2016). A summary of extinction risk of global freshwater fauna indicates that reptiles have the highest estimated risk among the six groups assessed (**Figure 6.18**). About a third of the more than 7,000 freshwater invertebrate species on the IUCN Red List are considered threatened, with gastropods being the most threatened group (Collen *et al.* 2012). These species combine to provide a wide range of critical services for humans, such as flood protection, food, water filtration and carbon sequestration (Collen *et al.* 2014).

Industrial-era agriculture results in nitrogen- and phosphorous-driven eutrophication of terrestrial, freshwater and nearshore marine ecosystems, and pesticide use can further degrade freshwater ecosystems (Malaj *et al.* 2014; Mekonnen and Hoekstra 2015). Globally, it is estimated that the number of lakes with harmful algal blooms will increase at least 20 per cent by 2050 (United Nations Educational, Scientific and Cultural Organization [UNESCO] 2014). Cyanobacterial algal blooms can result in lowered value for recreational uses, reduced aesthetics, lower dissolved oxygen concentrations, decline in drinking water quality and the production of toxins, which can impact both wildlife and human health (Brooks *et al.* 2016).

### 6.6.3 Grasslands

Grasslands cover about 8 per cent of total land area and were once home to some of the largest wildlife assemblages on Earth (IUCN 2017c). They are now considered the most altered terrestrial ecosystem worldwide and the most endangered

ecosystem on most continents, facing multiple pressures including land-use change, overgrazing, fragmentation, invasive species, suppression of natural fire, climate change and afforestation (IUCN 2017c).

Though grasslands contain high plant diversity, agricultural expansion is causing habitat destruction and fragmentation; for example, soybean production has replaced traditional livestock subsistence on natural pastures in much of the cerrado, a woodland savanna ecosystem, of South America (Aide *et al.* 2013). The Brazilian Cerrado holds roughly five per cent of global biodiversity and has lost close to 50 per cent of its original range (Brazil, Ministério de Meio Ambiente 2015). Rising temperatures are associated with woody encroachment and desertification across Africa (Midgley and Bond 2015; Engelbrecht and Engelbrecht 2016), South America and, to a lesser extent, Australia (Stevens *et al.* 2017).

It is estimated that 49 per cent of grassland ecosystems experienced degradation over a ten-year period (2000-2010), with nearly 5 per cent experiencing strong to extreme degradation (Gang *et al.* 2014), greatly decreasing the ability of these ecosystems to support biodiversity. Currently, 4.5 per cent of global grasslands have protected status (IUCN 2017c).

The strong relationship between grassland biodiversity and biomass (Cardinale *et al.* 2012), which is often used for animal fodder, agricultural products and raw textile materials for local populations, suggests that reductions in biodiversity will have negative implications for small-scale economic productivity and livelihoods.

**Figure 6.18: Extinction risk of global freshwater fauna by taxonomic group**

Note: Central vertical lines represent the best estimate of the proportion of species threatened with extinction, with whiskers showing confidence limits. Data for fish and reptiles are samples from the respective group; all other data are comprehensive assessments of all species (n = 568 crayfish, 1191 crabs, 630 fish, 57 reptiles, 490 mammals and 4147 amphibians).

Source: Collen *et al.* (2014).

## Box 6.5: Agrobiodiversity and gender

In many societies, women have traditionally been the keepers of deep knowledge of the plants, animals and ecological processes around them. The use of hybrid seed varieties (to which there has been a widespread shift in recent decades) can prevent women collecting seeds, undermining their status as seed collectors, as well as food security, especially in developing countries (Bhutani 2013). The erosion of biodiversity driven by industrial agriculture has therefore had specific impacts for women, including a loss of knowledge related to seeds, food processing and cooking (International Panel of Experts on Sustainable Food Systems 2016). In recent years, community seed banks that preserve local seeds have been re-established in some areas and are frequently managed by women, including through local seed exchanges. Participatory plant-breeding schemes to improve seeds further enhance women's status in farming (Galiè *et al.* 2017).

### 6.6.4 Agricultural landscapes

Beginning about 8,000 years ago, agricultural expansion and intensification has led to biodiversity loss in many biomes (United Nations Convention to Combat Desertification [UNCCD] 2017). Global demand and supply chains concentrate production in 'breadbasket' regions (Khouri *et al.* 2014), where landscape transformation reduces and fragments natural habitat, and yield-enhancing inputs (fertilizers and pest control) can impact non-cropped areas, watercourses and air quality. Recent decades are notable for marked land-use change in tropical regions associated with increasing oilseed production, in particular for soya and oil palm, much of which has come at the expense of highly biodiverse biomes (Foley *et al.* 2011). A dramatic decline in animal populations both inside and outside protected areas (Keesing and Young 2014) is associated with increased risk of predators attacking livestock (Zheng and Cao 2015; Malhi *et al.* 2016), negatively impacting agricultural livelihoods. Agricultural practices, such as tillage, crop combinations, and application of fertilizers and pesticides, also have impacts on below-ground biodiversity. (FAO and the Platform for AgroBiodiversity Research 2011, p. ix). Importantly, agricultural landscapes can sometimes maintain rare species in semi-natural habitats, while abandonment of agricultural practices may even lead to biodiversity decline (Plieninger *et al.* 2014).

Loss of diversity in agroecosystems increases their vulnerability and thus reduces the sustainability of many production systems. Reduction in the provisioning of regulating and support services can drive additional chemical use and may create harmful feedback loops (WHO and SCBD 2015, p. 5). There is some evidence that farmers in homogeneous landscapes have higher incomes than

farmers in heterogeneous landscapes (Watts and Williamson 2015), but their resilience to pressures such as climate change is often lower and income variability is greater (Abson, Fraser and Benton 2013). In addition, the homogenization of crop production has health impacts, contributing to the homogenization of diets and increasing consumption of processed foods associated with obesity and diet-related non-communicable diseases (Khouri *et al.* 2014). In contrast, production diversity is strongly associated with dietary and nutrition diversity among smallholder farmers whose market participation is limited (Sibhatu, Krishna and Qaim 2015) and local knowledge about seed varieties is often held by women farmers (see Box 6.5).

In some cases, intensive agriculture might also increase the prevalence of infectious diseases (Cable *et al.* 2017). For example, oil palm plantations in South America appear to increase the risk of Chagas disease (Rendón *et al.* 2015), and in Kalimantan, Indonesia, the burning of forests to plant oil palm may have contributed to the migration of bats, known to carry Nipah virus (Pulliam *et al.* 2011).

Biodiversity in agricultural landscapes is key to food and nutrition security (see Box 6.6). Pollination by about 100,000 species of insects, birds and mammals accounts for 35 per cent of global crop production (SCBD 2013; IPBES 2016), and up to 15 per cent of the value of economies based on cash crops (IPBES 2016, p. 209). Production is declining at local scales in places where the diversity of pollinators has been declining (IPBES 2016, pp. 154,185-186). Maintaining remnant patches within a few hundred metres of farms can help support pollinator populations and increase crop yield (Pywell *et al.* 2015; IPBES 2016, p. 394).

## Box 6.6: Importance of traditional practices and knowledge in pollinator conservation

Indigenous and local knowledge has been recognized as an important source of expertise in finding solutions to declines in animal pollinators – wild species such as birds, bats, bumblebees and hoverflies, and managed species such as honeybees (Lyver *et al.* 2015; IPBES 2016, p. xxii). In 2013, the Indigenous Pollinators Network was established with a view to combining traditional knowledge of indigenous peoples with modern science for the benefit of conserving pollinators and their vital services (Platform for AgroBiodiversity Research 2013). As well as conserving pollinators, traditional practices of beekeeping may have wider benefits for biodiversity, for example strengthening watershed conservation in the face of climate change (Kumsa and Gofu 2014) and in forest conservation (Wiersum, Humphries and van Bommel 2013).

Ethiopia is the largest producer of honey and beeswax in Africa (Begna 2015). These products are used for making candles and Tej or honey wine (an important drink in cultural life), and white honey from the Bale mountain region is used medicinally (IPBES 2016, pp. 312-314). Women contribute to this value chain, usually by manufacturing honey products rather than beekeeping itself. However, there is potential for beekeeping to provide income generation and empowerment for women in rural areas of Ethiopia (Ejigu, Adgaba and Bekele 2008; Serda *et al.* 2015).

### 6.6.5 Drylands

Though drylands are less diverse than other ecosystems, they contain thousands of species that are highly adapted to the dryland environment yet often neglected in conservation efforts. Arid and semi-arid rangeland ecosystems have seasonal climatic extremes and unpredictable rainfall patterns, but dryland species have evolved to be highly resilient by recovering quickly from drought, fire and herbivore pressure. Desertification (also known as land degradation in drylands) is a worldwide phenomenon (see Section 8.4.2).

Dryland degradation has many causes, including human conflicts. Large amounts of waste, garbage and toxic material were dumped and burned in desert ecosystems due to the Islamic Republic of Iran-Iraq war (UNEP 2016f). Drought, overgrazing, overuse of groundwater and unsustainable agricultural practices impose additional pressures (O'Connor and Ford 2014; Southern Africa Development Community 2014), though the extent of human versus natural causes are often difficult to disentangle.

The degradation of semi-arid and arid landscapes reduces capacity in terms of freshwater supply and food production, decreases wild food availability, and presents a threat to emblematic species and genetic resources (Low *et al.* 2013). Desertification has a damaging effect on soil health and vegetation, leading to adverse impacts that cascade through the food chain (Assan, Caminade and Obeng 2009). Salinization, mostly due to unsustainable irrigation systems, irrigated areas with poor drainage and poor quality of irrigation water, is a major problem in arid and semi-arid regions (see Section 9.5.6). The almost complete desiccation of the Aral Sea has led to the creation of the Aral Kum desert, which has caused degradation of riparian forests, pastures and other vegetation cover (Kulmatov 2008).

### 6.6.6 Forests

Forests provide habitat for large numbers of animal and plant species, and deforestation is one of the top threats to species diversity (FAO 2015b; Alroy 2017). Deforestation and forest degradation continue in many regions, often in response to demands for biomass as well as drivers outside the forest sector, such as urban expansion and agriculture, energy, mining and transportation development (see Section 8.4.2). Recent estimates show that tree cover loss is high across all forest types but differs across regions (Leadley *et al.* 2014). Tree cover density is associated with both losses and gains, but losses are especially high in the tropics and boreal forests; tropical rainforest accounted for 32 per cent of global tree cover loss over the period 2000-2012, with half of this loss occurring in South America (Hansen *et al.* 2013). Rates of forest gains approach or exceed rates of tree cover loss in some areas, particularly in temperate regions, reflecting forestry-dominated land management.

Recent work suggests that more biodiverse forests contribute a greater range of ecosystem services (Gamfeldt *et al.* 2013). Forests supply essential regulating services, including carbon sequestration, important for the regulation of climate, and protection of soil and water (Foley *et al.* 2007; Brockerhoff *et al.* 2017). With increasing deforestation and forest degradation,

however, forest ecosystems can transform from net carbon sinks to carbon sources (Baccini *et al.* 2017).

The total number of people deriving benefits from forests – in the form of food, forest products, employment, and direct or indirect contributions to livelihoods and incomes – is estimated to be between 1 billion and 1.5 billion (Agrawal *et al.* 2013). In Africa, approximately 80 per cent of people are dependent on fuelwood (including charcoal) as their sole source of energy (UNEP 2016a, p. 76). Global exports of forest products were worth US\$226 billion in 2015, with wood fuel comprising 9 million m<sup>3</sup> and industrial roundwood 122 million m<sup>3</sup> (FAO 2015b). Non-wood forest products, including wild plant resources, typically contribute less to local economies, but can have high global market value. Contributions of forests to economies of the developing world are estimated at over US\$250 billion (Agrawal *et al.* 2013). These economic benefits can only be maintained if forests are managed sustainably (FAO 2015a).

Though there are short-term employment gains from deforestation, the loss of forests translates into a loss of livelihoods: over 13 million people are employed in the formal forest sector, and another 40-60 million people may be employed in informal small and medium-sized forest operations (Agrawal *et al.* 2013; FAO 2018c). A well-documented gender gap in access to forest resources suggests that poor management or loss of forest ecosystems may have different impacts on women and men (WWF 2013; Djoudi *et al.* 2015).

The direct health consequences of deforestation are complex: there is some evidence that forests can promote physical and mental well-being (Oh *et al.* 2017), while forest loss may increase exposure to infectious diseases, including malaria (Guerra, Snow and Hay 2006; Fornace *et al.* 2016) and other vector-borne parasites (Plowright *et al.* 2015; Hunt *et al.* 2017; Olivero *et al.* 2017).

### 6.6.7 Mountains

Mountain ranges cover around 22 per cent of the terrestrial space of the planet and provide multiple ecosystem services. At lower elevations, mountain habitats, especially those in tropical regions, are often more biodiverse and have higher levels of endemism than adjacent lowlands. However, habitat degradation and fragmentation has impacted many mountain ecosystems (Shrestha, Gautam and Bawa 2012; Chettri 2015; Venter *et al.* 2016) (see Section 4.3.2).

Mountain ecosystems are especially vulnerable to climate change: effects include shifts in species ranges and composition, with notable impacts on those organisms whose dispersal might be limited, or which are restricted to high altitudes, and local extinctions can occur for species in the upper margins of elevation gradients (Pauli *et al.* 2012; Khan *et al.* 2013; Grytnes *et al.* 2014; Knapp *et al.* 2017). Climate-induced warming can change ecosystem functioning, advance spring phenology, and increase productivity and carbon uptake (Piao *et al.* 2012; Shen *et al.* 2016). Localised pressures include road construction, deforestation, mining, tourism, grazing of domestic livestock, burning and armed conflict (see Epple and Dunning 2014; Young 2014).

**Figure 6.19: Capacity of mountains to provide ecosystem services**

The maps display the proxy capacity of land to provide ecosystem services, measuring to what degree 15 selected ecosystem services are supported by the underlying land characteristics: (a) global analysis; (b) population density data highlighting regions of high demand for ecosystem services; (c) and (d) high supply of and high demand for ecosystem services in the Himalayas.

Source: Grêt-Regamey, Brunner and Kienast (2012).

Most mountain areas today are under high human pressure, including the Tropical Andes and Central Asian Mountain biodiversity hotspots. The Himalayas, with approximately 19,000 species (Khan *et al.* 2013), have been documented as highly vulnerable to climate change (Shrestha, Gautam and

Bawa 2012). In Europe, warming has driven many species upward, resulting in local increases of boreal and temperate mountaintop diversity; but the opposite effect has been noted for Mediterranean mountains, which have lost some species (Pauli *et al.* 2012). In some areas, the abandonment of agricultural land in mountain ranges has also led to decreases in biodiversity, especially among bird populations (Hussain *et al.* 2018).

Loss of biodiversity reduces nature's contributions to people in both mountains and lowlands (**Figure 6.19**) (Grêt-Regamey, Brunner and Kienast 2012). Degradation in mountain ecosystems will result in changes in air quality and climate regulation, such as the reduction of greenhouse gas sequestration (Ward *et al.* 2014). Threats to local communities include loss of food security, medicinal plants, and water quality and provision, and increased exposure to risks associated with landslides, sedimentation of rivers and flooding modifying their livelihoods and land cover (Eriksson *et al.* 2009; Khan *et al.* 2013; Young 2014). A few mountain areas still maintain the traditional use of species (e.g. Andes, Himalayas), while ethnobotanical knowledge in the Alps has been lost due to changes in land-use patterns (Khan *et al.* 2013). Glacier loss impacts water security, with some populations in South Asian countries dependent upon the flow of rivers from the western but also central and eastern Himalayas (Khan *et al.* 2013; see **Box 6.7**). Economic costs of land-use change may also be high; for example, a 75 per cent reduction in economic benefits from nature-based recreation has been reported following replacement of mountain forest with crops in Nepal (Thapa *et al.* 2016).

#### 6.6.8 Polar regions

Biodiversity in the Arctic and Antarctic regions is under particular stress (Bennett *et al.* 2015) (see Section 4.3.2). Many native species are in decline; rising temperatures and invasive species, especially in the sub-Antarctic and Antarctic Peninsula, are major pressures (Hughes, Cowan and Wilmoth 2015; Amesbury *et al.* 2017). Industrial development, pollution and local disturbances present additional pressures (Conservation of Arctic Flora and Fauna [CAFF] 2013), with polar regions acting as a sink for many anthropogenic pollutants such as persistent organic pollutants (POPs) and other synthetic organic chemicals (Alava *et al.* 2017).

#### Box 6.7: Climate change and the need for ecosystem-based adaptation: the Hindu Kush Himalayas

While climate change may bring some benefits to mountain regions (e.g. longer growing seasons), the preponderance of impact is negative. Increased variability in precipitation patterns (including variability in monsoon and more frequent extreme rainfall) coupled with glacial ice melt, is predicted to increase risks of floods (carrying rock, sediments and debris), landslides, fire, soil erosion and spread of water-related and vector-borne diseases (Ebi *et al.* 2007; Armstrong 2010; Ahmed and Suphachalasai 2014). Of particular concern are the potentially devastating impacts from glacial lake outburst floods which have become more frequent since the middle of the 20th century (Armstrong 2010; International Centre for Integrated Mountain Development 2011).

The Hindu Kush Himalayas, the greater Himalayan region extending from eastern Nepal and Bhutan to northern Afghanistan, are among the most extensive areas covered by glaciers and permafrost on the planet. They contain water resources that drain through ten of the largest rivers in Asia, from which over 1.3 billion people derive their livelihoods and upon which many more depend for water and other resources (Eriksson *et al.* 2009). The region has been recognized as a unique biodiversity-rich area with equally unique topographic characteristics and socioeconomic and environmental challenges. The accelerated rate of warming, glacier ice melt and related implications on the hydrological systems are among the most pressing challenges to this unique mountain ecosystem (Gerlitz *et al.* 2017). It is essential that these macro-climatic effects are integrated into plans to conserve the fragile biodiversity of the region.

Substantial changes expected to Antarctic ice sheets before the turn of the century may have considerable global consequences (Chown *et al.* 2017) (see Section 4.3.2). Under most climate scenarios, the Arctic is projected to be ice-free in summer by 2050 (IPCC 2013, p. 1090), although remnants of multi-year ice will remain off the coasts of Canada and Alaska. The retreat of sea ice is likely to result in major ecological shifts linked to:

- a) an increase in primary productivity as a result of more open water and greater freshwater flow carrying nutrients;
- b) a comparable shift in the source and quality of food for species at higher trophic levels such as krill, fish and marine mammals (Frey *et al.* 2016; Alsos *et al.* 2016); and
- c) an influx of new species into the polar regions with productivity and food web relationships changing as coastal and sea ice systems of polar regions experience earlier spring bloom and longer growing periods for microalgae (Potts *et al.* 2016).

Average abundance of Arctic vertebrates increased from 1970 until 1990 and then remained fairly stable through to 2007, as measured by the Arctic Species Trend Index (McRae *et al.* 2012; CAFF 2013). However, some food resources are being lost in areas of diminishing sea ice, posing health risks to species such as the walrus, ivory gull, polar bear and Barents Sea harp seal (CAFF 2017). Penguins are one of the more regularly monitored species groups in Antarctica, and populations have been changing over the last century with recorded declines in some colonies of macaroni, Adélie and chinstrap penguins (Trathan, Lynch and Fraser 2016).

It is likely that, due to higher productivity, the availability of some natural resources will increase for circumpolar peoples and communities (Arrigo 2014), but changes in hunting conditions will have a detrimental impact on the Inuit and other groups that have relied on seal hunting and other traditional food sources for which sea ice provides access. Some negative impacts are already being felt; for example, a significant die-off of seals and walruses in the Pacific Arctic in 2011 affected food sources for indigenous communities in the United States of America, Canada and Russian Federation (CAFF 2017). Breaks in the dormancy of pathogenic bacteria and viruses in thawing permafrost are a direct threat to human health (Sutherland *et al.* 2018).

The opening of potential new fishing zones, oil and gas development and shipping may result in future conflicts, especially with regard to economic use, governance, cultural interests and marine protected areas. As the Antarctic has no indigenous people or local communities and is outside the range of the Convention on Biological Diversity's Nagoya Protocol, the equitable sharing of benefits from biodiversity to people, including those benefits derived from bioprospecting, represents a particular challenge not completely addressed by the Antarctic Treaty System (Chown *et al.* 2017).

## 6.7 Responses

A broad spectrum of governance approaches and policy instruments are used to help address biodiversity loss. Their effectiveness and specific examples are explored in Chapter 13.

### 6.7.1 The Convention on Biological Diversity (CBD)

The CBD has been the key global convention on biodiversity in recent decades and it has three central goals: the conservation of biological diversity, the sustainable use of its components, and the fair and equitable sharing of the benefits arising out of the utilization of genetic resources. With 196 Parties in 2018, it establishes international norms and provides a forum for states to cooperate and share information and coordinate policy. In 2010 member states adopted the Strategic Plan for Biodiversity 2011-2020, as well as the more specific Aichi Biodiversity Targets, a comprehensive and ambitious array of goals subsequently reflected in many of the United Nations Sustainable Development Goals (SDGs). The midterm assessment of progress towards the Aichi Biodiversity targets concluded that, while progress has been made, it was insufficient to achieve them by 2020 (SCBD 2014).

The CBD's Cartagena Protocol on Biosafety deals with the international transfer of living modified organisms (LMOs), demanding advanced and 'informed' agreement from the importing country prior to the exchange of any LMOs, which includes genetically modified organisms (GMOs) such as seeds. The Nagoya Protocol on Access to Genetic Resources and the Fair and Equitable Sharing of Benefits Arising from their Utilization to the Convention on Biological Diversity establishes a framework for access to genetic resources and the sharing of benefits arising from their utilization, including the transfer of relevant technologies, which directly aims to curb biopiracy and promote equity in future bioprospecting agreements. It has been ratified by 105 countries as of May 2018. The Secretariat of the CBD plays a key role in raising awareness and organizing regional workshops and other capacity-building exercises.

An important mandatory requirement of Parties to the CBD is a commitment to produce National Biodiversity Strategies and Action Plans (NBSAPs) with associated targets (see Chapter 13.1). The Global Environment Facility (GEF), through its enabling activities window, provides support to eligible Parties which focuses on revising/updating their NBSAPs considering the CBD Strategic Plan for Biodiversity 2011-2020 and the Aichi Biodiversity Targets. This support is routed through the United Nations Development Programme (UNDP) and UN Environment (UNEP) as the key implementing agencies (Pisupati and Prip 2015). The CBD also supports the creation of subnational biodiversity strategies and action plans and regional (supranational) plans, and collaborates with the other key multilateral environmental agreements that have biodiversity-related mandates such as the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) (see **Box 6.8** and Annex 6-1).

### 6.7.2 Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES)

In 2012, IPBES was officially established with a stated mission "to strengthen the science-policy interface for biodiversity and ecosystem services/nature's contributions to people for the conservation and sustainable use of biodiversity, long-term human well-being and sustainable development." IPBES is organized under the auspices of four United Nations agencies – UNEP, United Nations Educational, Scientific

## Box 6.8: The international wildlife trade and CITES

The Convention on International Trade in Endangered Species of Wild Flora and Fauna (CITES) came into force in 1975 and had 183 Parties by 2018. International trade of flora and fauna is worth billions of dollars and includes hundreds of millions of species and species parts, including food products, artistic ornaments and many traditional medicines (Broad, Mulliken and Roe 2003; Rosen and Smith 2010). Today, the agreement assigns various degrees of protection to over 35,000 species of plants and animals (CITES 2018).

Species listed in CITES that are traded across borders are subject to controls through a licensing system managed by member countries. CITES species are listed in three Appendices attached to the Convention: Appendix I provides the highest degree of protection, effectively banning all commercial trade in wild-taken alive or dead specimens of the species; trade in specimens on Appendix II is strictly regulated; Appendix III indicates a country has unilaterally asked for the help of other Parties in controlling trade in the species, subject to regulation within its jurisdiction.

The CITES agenda is ambitious, and the Convention is not self-executing: parties must implement and enforce its provisions under national law. This is a difficult task requiring significant educational and enforcement resources, and corruption can be problematic (Bennett 2015).

and Cultural Organization (UNESCO), Food and Agriculture Organization of the United Nations (FAO) and UNDP – and is administered by UNEP. By June 2018, its membership comprised 130 governments as well as a number of major stakeholder groups.

### 6.7.3 Protected areas

Protected areas have been successful in reducing habitat loss (Aichi Biodiversity Target 5) and have helped in lowering extinction risk for some target species (Aichi Target 12) (UNEP-WCMC and IUCN 2018). However, despite clear evidence that investment in conservation can help reduce biodiversity loss (Geldmann *et al.* 2013; Waldron *et al.* 2017), less than 15 per

cent of the world's terrestrial and inland waters, less than 11 per cent of the coastal and marine areas within national jurisdiction, and less than 4 per cent of the global ocean is covered by protected areas (**Figure 6.20**) (UNEP-WCMC and IUCN 2018; Sala *et al.* 2018). In addition, a third of the land area within protected area boundaries is already degraded by human impacts (Jones *et al.* 2018).

While providing biodiversity benefits, protected areas can have potentially negative effects on livelihoods in local communities due to decreased access to natural resources or the lack of support for the development of cultural, social, financial, natural, human, physical and political capital assets (Bennett and Dearden 2014). This can result in ineffective management,

Figure 6.20: Protected areas of the world

Source: UNEP-WCMC and IUCN (2018).

### Box 6.9: Biodiversity conservation and poverty

It is increasingly accepted that biodiversity loss and poverty are closely coupled problems, though seeking to solve one does not automatically address the other (SCBD 2010; Suich, Howe and Mace 2015). Indeed, some approaches to protecting particular species or natural areas have exacerbated existing uneven access to natural resources and placed disproportionate burdens on already-vulnerable populations (Dowie 2009; Sylvester, Segura and Davidson-Hunt 2016). Intergenerational justice is also an important theme, since loss of biodiversity will impoverish future generations in a variety of ways, including reducing their ability to rely upon and connect with a biodiverse natural world.

Biodiversity conservation is likely to be more effective in programmes that successfully integrate social and ecological support, and the benefits from conservation are more likely to be directly accessible by local human populations (Figurel, Durán and Bray 2011; Persha, Agrawal and Chhatre 2011; Fischer *et al.* 2017).

equity issues, lack of accountability or conflict (Halpern *et al.* 2014; Watson *et al.* 2014; Di Minin and Toivonen 2015; Eklund and Cabeza 2017; see also **Box 6.9**). The active engagement of indigenous and local communities in the decision-making process has proven highly effective at addressing these imbalances (see **Box 6.10**). Analysis of deforestation rates indicate that these can be significantly lower in community-managed forests in comparison to strictly protected areas (Porter-Bolland *et al.* 2012). The development of a more inclusive and integrated approach linking communities with national, divisional and provincial governments for sustainable development has proved highly efficient (see Locally Managed Marine Areas case study in Fiji in Section 13.2.1). Increasingly, indigenous and local communities' contributions and collective actions have the potential to be scaled up and to inform national and international practice and provide a practical governance approach as an alternative to top-down policy-setting.

#### 6.7.4 Other approaches

Many other approaches have evolved to confront biodiversity loss and respond to related drivers. Biodiversity offsets create biodiversity benefits to compensate for losses (Gordon *et al.* 2015; Apostolopoulou and Adams 2017). Controversially based on the monetization of nature (Adams 2014; Costanza *et al.* 2017), offset programmes have been developed in numerous countries within the last ten years. Monetary valuation can serve as a useful tool in underpinning policy instruments such as socioeconomic assessments of public policies and investments, and economic incentives such as

payment for ecosystem services, permits and taxation schemes (Bateman *et al.* 2013; Gaworecki 2017). Another economic instrument is the United Nations System of Environmental-Economic Accounting (Experimental Ecosystem Accounting), developed in 2012. Examples of ecosystem accounting have been prepared (e.g. Victoria in Australia, Uganda, and the United Kingdom of Great Britain and Northern Ireland; Eigenraam, Chua and Hasker 2013; UNEP-WCMC and Institute for Development of Environmental-Economic Accounting [IDEEA] 2017; United Kingdom Office for National Statistics 2018), and initiatives to encourage its use in planning have been launched (see <https://www.wavespartnership.org> and <https://naturalcapitalcoalition.org/>).

Efforts to address deforestation and forest degradation in developing countries culminated in international agreement under the United Nations Framework Convention on Climate Change (UNFCCC) on methodological guidance for implementing activities relating to reducing emissions from deforestation and forest degradation (REDD) and the role of conservation, sustainable management of forests and enhancement of forest carbon stocks in developing countries – known as REDD+ (UNFCCC 2018). Forest certification, such as that promoted by the Forest Stewardship Council (<https://www.fsc.org/>) and the Programme for the Endorsement of Forest Certification (<https://www.pefc.org/>) provides greater information flow to consumers, encompassing not just logging and extraction but also the social and economic well-being of workers and local communities (e.g. forest management certification

### Box 6.10: Female rangers in South Africa

In 2015, a South African ranger group consisting mostly of women, the Black Mamba Anti-Poaching Unit, was one of the winners of the top United Nations environmental prize. The unit was formed in a bid to engage local communities outside conservation parks in protecting biodiversity inside the fences. Initially comprising 26 unemployed female high-school graduates, the unit has reduced snaring by 76 per cent since its launch in 2013, removed more than 1,000 snares, and put five poachers' camps and two bushmeat kitchens out of action (United Nations 2015).

[http://www.blackmambas.org/uploads/8/3/5/5/83556980/screen-shot-2016-07-18-at-4-34-38-pm\\_orig.png](http://www.blackmambas.org/uploads/8/3/5/5/83556980/screen-shot-2016-07-18-at-4-34-38-pm_orig.png)

in Indonesia; Miteva, Loucks and Pattanayak 2015), and transparency and inclusiveness in decision-making. In the European Union (EU) Common Agricultural Policy, some mechanisms have been developed to address environmental problems through protecting and promoting biodiversity in the European countryside.

Within urban settings, a movement towards 'green cities' is gathering pace, especially, but not only, within developed countries (Hegazy, Seddik and Ibrahim 2017), which highlights the protection and expansion of urban forests and green spaces and parks, and the recreational and air quality benefits they provide to people (Salbitano *et al.* 2016), including increased exposure to microbial biodiversity, important for healthy immune responses (Lax, Nagler and Gilbert 2015). Public engagement in urban agriculture, and specific programmes on beekeeping and bird conservation can facilitate human contact with nature in an urban setting. Urban and peri-urban agriculture, when guided by principles of agroecology, with wastes (or by-products) reused as raw materials, promotes self-sufficiency, gender equality, disaster resilience, water and soil conservation and environmental sustainability (FAO 2001; van Veenhuizen 2012).

More generally, ecosystem-based adaptation (EbA) promotes the conservation, sustainable management and restoration of natural ecosystems to help people and communities adapt to climate change (Cohen-Shacham *et al.* 2016). However, the effective integration of EbA is challenged by scientific uncertainty at the international scale and disputes over criteria for prioritization (Ojea 2015; Bourne *et al.* 2016).

Ocean governance is particularly complex. Current efforts are focused on the elaboration of the text of an international legally binding instrument under the United Nations Convention on the Law of the Sea on the conservation and sustainable use of marine biological diversity of areas beyond national jurisdiction (ABNJ).

## 6.8 Conclusion

Our understanding of the natural world and the threats posed to its integrity has never been greater. New technologies have allowed us unparalleled insight into the different dimensions of biodiversity, from genomes to biomes. The major pressures on biodiversity are increasingly well-understood – habitat transformation/land-use change, invasive species, pollution, overexploitation including the illegal wildlife trade and climate change – though each of the world's biomes faces distinct challenges, reflecting particular geographic, ecological and socioeconomic contexts. Biodiversity loss is exacerbated where there is significant inequality in wealth and is a major threat to intergenerational justice. But the political and social will necessary to preserve biological diversity has been lacking. While certain policy responses have demonstrated effectiveness in promoting biodiversity conservation, persistent negative trends in almost every aspect of biodiversity indicate the need for more concerted action. Wildlife populations are thinning, reducing their adaptive potential; current rates of species extinctions are estimated to be orders of magnitude greater than background rates, with some scientists suggesting that we may be entering a sixth mass extinction event, and ecosystems are becoming increasingly degraded.

Increased investment in conservation on a global scale is urgently required. Greater focus on strengthening governance systems; improving policy frameworks through research; integration, implementation and effective enforcement; and encouraging partnerships and participation, are all measures that have the potential to address the greatest pressures on biodiversity. Efforts to combat biodiversity loss must also address poverty eradication, gender inequality, systemic corruption in governance structures and other social variables. The path to conserving global biodiversity and to finding solutions for sustainable use is a long but critical journey; humankind depends on it to support nature's contributions to people and the flourishing of health and development.

## Executive summary

**Human pressures on the health of the oceans have continued to increase over the last decade, in concert with the growing human population and the expanded use of ocean resources** (*well established*). Multiple stressors give rise to cumulative impacts that affect the health of marine ecosystems and diminish nature's benefits to humans. However, there has been success in the management of some pressures, with concomitant improvements in ocean health, and these provide lessons on which to build. Out of numerous existing pressures we have selected three for particular attention in this Global Environment Outlook (GEO-6) assessment: bleaching of coral reefs; marine litter; and challenges to achieving sustainable fisheries in the world's oceans. {7.1}

**Tropical coral reefs have passed a tipping point whereby chronic bleaching has killed many reefs that are unlikely to recover even over century-long timescales** (*well established*). Coral bleaching is due to warming of the oceans, which is in turn, attributed to anthropogenic emissions of green house gases (GHGs; especially CO<sub>2</sub>) since the industrial revolution. Ocean warming lags behind GHG emissions by several decades, such that the tipping point for coral reef bleaching was passed in the 1980s when atmospheric concentration of CO<sub>2</sub> exceeded about 350 parts per million (ppm). {7.3.1}

**Reef bleaching events now have a recurrence interval of about six years, while reef recovery rates are known to exceed ten years** (*established but incomplete*). This means that, on average, reefs will not have sufficient time to recover between bleaching events and so a steady downward spiral in reef health is to be expected in coming decades. The oceans SDG target 14.2 "by 2020, sustainably manage and protect marine and coastal ecosystems to avoid significant adverse impacts, including by strengthening their resilience, and take action for their restoration in order to achieve healthy and productive oceans" may not be attainable for most tropical coral reef ecosystems. {7.3.1}

**There is evidence that reef death will be followed by loss in fisheries, tourism, livelihoods and habitats** (*inconclusive*). The demise of tropical coral reef ecosystems will be a disaster for many dependent communities and industries, and governments should, over the next decade, prepare for the eventual collapse of reef-based industries. The contributions provided by coral reefs have collectively been valued at US\$29 billion, which includes their value to tourism, fisheries and coastal protection. Losses to these sectors have not yet been documented but there is significant risk that losses will occur over the next decade. {7.4.1}

**Fisheries and aquaculture are estimated to be worth US\$362 billion in 2016, with aquaculture contributing US\$232 billion** (*established but incomplete*). Mariculture is expanding but most of the increase is in aquaculture, especially inland aquaculture (*established*). Aquaculture provides more than 10 per cent of the total tonnage of fish production and this proportion is increasing. Together fisheries and aquaculture support between 58-120 million livelihoods, depending on how part-time employment and employment in secondary

processing is counted. The large majority of livelihoods are provided by small-scale fisheries and this has been stable for over a decade, yet commercial harvesting accounts for the large majority of commodity value, including more than US\$80 billion per year exported from developing countries to international markets. {Table 7.1, 7.3.2}

**Fish, high in protein and micronutrients important for health, currently provide 3.1 billion people with over 20 per cent of their dietary protein, with higher proportions in many areas of the world where food insecurity is widespread** (*established but incomplete*). To meet future challenges of food security and healthy populations, in addition to using all natural products harvested for food more efficiently, more fish, invertebrates and marine plants will have to be taken as food from the oceans and coasts, so both capture fisheries and aquaculture are expected to expand. {7.5.2}

**It is possible to keep capture fisheries sustainable, but this requires significant investments in monitoring, assessment and management and strong local community-based approaches** (*established but incomplete*). Likewise, sustainable aquaculture requires knowledge and care in management of operations. {7.6}

**Reviews show wide variation among countries in the sustainability of their fisheries and aquaculture, with factors such as overall wealth to invest in fisheries research and management, while avoiding capacity-enhancing subsidies, strongly affecting the ability to keep large-scale fisheries sustainable** (*established but incomplete*). For small-scale fisheries coherence of the social structures and cultural practices that promote effective community self-regulation strongly affect sustainability. {7.5.2}

**The ecosystem approach to fisheries has been widely adopted in national and regional policies and operational guidance on actions to manage the footprint of fisheries has been provided by the Food and Agriculture Organization of the United Nations (FAO)** (*inconclusive*). Despite the acknowledgement of the large footprint of fisheries on marine ecosystems and its full uptake in policy, measures to minimize the ecosystem effects of fishing have had mixed success. However, as with sustainability of exploitation of target species, in general the ecosystem footprint of by-catches, discards and negative habitat impacts of fishing gear is declining in the parts of world with sufficient economic resources to invest in fisheries monitoring and gear technologies that improve selectivity of harvest and reduce habitat impacts. This approach is also being applied in aquaculture, with comparable objectives and rapid uptake by the industry. {7.4.2}

**The amount of marine litter continues to increase – an estimated 8 million tons (Mt) of plastics enters the ocean each year, as a result of the mismanagement of domestic waste in coastal areas** (*established but incomplete*). Marine litter has been found at all ocean depths. Without intervention, the quantity of plastic in the ocean is expected to increase to 100-250 Mt by 2025. {7.3.3}

**Plastic particles are increasingly being found in the digestive systems of marine organisms including fish and shellfish consumed by humans** (*established but incomplete*). The human health risks of ingesting seafood contaminated with plastic are unclear. There is well-documented evidence of physical damage to marine organisms from both entanglement in marine litter and ingestion of plastic. Some plastic contains potential toxins and can also adsorb and concentrate toxic substances from the surrounding seawater. However, there is currently no evidence of serious toxic effects to marine biota from these pollutants. Marine litter can also provide a means of transport for the spread of pathogens and invasive species (*well established*). {7.4.4}.

**The economic, social and environmental costs of marine litter are continually increasing and include the direct economic costs of clean-up and loss of revenue from industries such as tourism and fishing** (*unresolved*). Social and health costs are more difficult to quantify beyond local scales, as are environmental costs such as reduction in ecosystem function and services. {7.4.4}.

## 7.1 Introduction

The world's oceans comprise more than 70 per cent of the Earth's surface. More than 1.9 billion people lived in coastal areas in 2010, and the number is expected to reach 2.4 billion by 2050 (Kummu *et al.* 2016). Twenty of the 30 megacities<sup>1</sup> are located on coasts, and these megacities are expected to increase in population faster than non-urban areas (Kummu *et al.* 2016). The three fastest-growing coastal megacities are Lagos, Nigeria (4.17 per cent population growth rate), Guangzhou, China (3.94 per cent) and Dhaka, Bangladesh (3.52 per cent) (Grimm and Tulloch eds. 2015).

### 7.1.1 Welcome to the ocean

The health and livelihoods of many people are directly linked to the ocean through its resources and the important aesthetic, cultural and religious benefits it provides. Seafood provides at least 20 per cent of the animal protein supply for 3.1 billion people globally (Food and Agriculture Organization of the United Nations [FAO] 2016a). This is particularly important for economically disadvantaged coastal areas and communities. Coastal ecosystems also provide numerous benefits not readily monetized, such as coastal stabilization, regulation of coastal water quality and quantity, biodiversity and spawning habitats for many important species. The ocean is an integral part of the global climate system (Intergovernmental Panel on Climate Change [IPCC] 2013), contributing to the transport of heat, which influences temperature and rainfall across the planet. About 50 per cent of global primary production occurs in the ocean (Mathis *et al.* 2016). The ocean also provides a reservoir of additional economically important resources such as aggregates and sand, renewable energy and biopharmaceuticals. However, people, their livelihoods and the many indirect benefits the ocean provides are being affected by the deteriorating health of marine and coastal ecosystems, from causes including pollution, climate change, overfishing, and habitat and biodiversity loss.

By definition a healthy ocean would be one in which the basic ecosystem function and structure are intact, thereby:

- ❖ able to support livelihoods and contribute to human well-being;
- ❖ resilient to current and future change.

The full range of benefits can only continue to be enjoyed if marine and coastal ecosystems are functioning and used within environmental limits, in a way that does not cause severe or irreversible harm. However, sustainable use of marine and coastal ecosystems is challenged by many drivers of change (see Chapter 2), and by the competing pressure on natural resources and the complexities of governance and multiple, often conflicting, uses (Figure 7.1). Coastal states have rights and obligations within their marine jurisdiction (United Nations 1982). However, the ocean imposes special challenges on the exercise of jurisdiction. Ocean currents can carry chemicals, waste, emerging organic pollutants and

pathogens beyond areas under national maritime boundaries, and marine organisms and seabirds may not stay within an area under the jurisdiction of a state. Coordination of governance measures is particularly difficult in areas beyond national jurisdiction, where a large number of institutions and agreements regulate sectoral issues such as shipping, fishing and seabed mining.

Not only must states cooperate across borders, they must also integrate decision-making across the various uses of marine and coastal ecosystems. The interlinkages between ocean conditions and marine life, and the spatially dynamic ocean processes mean that the activities of any single industry sector may have far-reaching impacts. These may disrupt the livelihoods of people who have received no benefits from the industry that has caused the impact. Similarly, benefits expected from conservation measures taken in one sector or jurisdiction may be reduced or negated by lack of action in other sectors or jurisdictions.

Global challenges such as climate change and ocean acidification must also be addressed. Climate change impacts ocean temperature, sea-ice extent and thickness, salinity, sea level rise and extreme weather events. Although climate change impacts vary at regional levels and therefore require adaptive management actions at local and regional scales (Von Schuckmann *et al.* 2016), these efforts need to be coordinated at larger scales, and lessons and best practices shared efficiently.

### 7.1.2 Focus of this chapter

Oceans have many uses, and there are too many linkages among marine ecosystems and between the land and adjacent seas to review them all in this chapter. *The First Global Integrated Marine Assessment* (A/RES/70/235; Inniss and Simcock eds. 2016) and reports of the Intergovernmental Panel on Climate Change (IPCC 2013) have provided recent comprehensive reviews of the state of the ocean. Therefore, three topics have been selected here that warrant particular attention – tropical coral reefs, fishing and debris entering the marine environment. Several topics of emerging or particular interest – mercury, sand mining, deep sea mining and ocean noise – are also briefly considered.

The rationale for selecting the three main topics stems from resolutions adopted by the United Nations Environmental Assembly (UNEA) at its second session in May 2016, which included specific mention of coral reefs in Resolution UNEP/EA.2/Res.12 (UNEA 2016a), and marine litter in Resolution UNEP/EA.2/Res.11 (UNEA 2016b). Marine litter was also included in a special Decision CBD/COP/DEC/XIII/10 of the Conference of the Parties to the Convention on Biological Diversity (CBD) (CBD 2016) and in Decision BC 13/17 of the Conference of the Parties to the Basel Convention (2017). Fisheries have linkages to multiple Sustainable Development Goals (SDGs) and they also intersect the cross-cutting themes identified in Chapter 4 (notably gender, health, food systems, climate change, polar regions, and chemicals and waste).

<sup>1</sup> Cities with populations of more than 10 million.

Figure 7.1: Generalized schematic showing the drivers and pressures relevant to the marine environment

The central circle represents major high-level drivers of change in human demands on the ocean. The inner ring represents the types of societal needs promoted by the drivers, and the outer ring represents the industry sectors addressing the needs, for which policies are commonly established. The needs expressed through sector actions are the relevant pressures.

## 7.2 Pressures

Human activities can alter the ocean and its resources in many ways, particularly through activities that are land-based. Part V of the *First Global Integrated Marine Assessment* (Inniss and Simcock eds. 2016) describes both the societal benefits and major impacts of human activities, whether directly through resource extraction (e.g. fish, hydrocarbons, sand) or indirectly

(e.g. seabed impacts of fishing gear or mining operations). The report also documents the economic value and number of livelihoods supported by each industry sector (**Table 7.1**)

The footprints of many ocean industries overlap (**Table 7.1**: column 4) and sometimes multiple sectors use the same resource for different purposes (e.g. fish for ecotourism, versus food for a coastal community; see also Halpern *et al.* 2012).

**Table 7.1: Estimates of economic value, employment and major environmental impacts of the major ocean-related industries**

| Sector [and World Ocean Assessment chapter] | Economic value or scale of operation                                                                                                            | Employment/ livelihoods                                                                                                                                                                             | Major environmental impacts if inadequately regulated                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fishing [9,11,12]                           | US\$362 billion (includes mariculture and freshwater aquaculture – approx. US\$28 billion but accounting not fully separated)<br>Competent IGOs | 58-120 million (depending on how part-time employment and secondary processing employment are counted)                                                                                              | Changes of food web structure and function if top predators or key forage species are depleted or fishing is highly selective.<br>By-catches of non-targeted species, some of which can sustain only very low mortality rates (e.g. sea turtles, many seabirds and small cetaceans).<br>Gear impacts on seabed habitats and benthos, especially structurally fragile habitats (e.g. corals, sponges).<br>Continued fishing of lost fishing gear.                                                                                                                                                |
| Shipping [17]                               | 50,500 billion ton-miles of cargo;<br>2.05 billion passenger trips<br>Competent IGO – and conventions – IMO and MARPOL                          | > 1.25 million seafarers                                                                                                                                                                            | Shipping disasters and accidents that may result in release of cargos, fuel and loss of life. Toxicity of cargos ranges from nil to severe.<br>Chronic and episodic release of fuel and other hydrocarbons.<br>Infrequent loss of containers with toxic contents.<br>Discharge of sewage, waste and 'grey water'.<br>Transmission of invasive species through ballast water and bilge water.<br>Use of anti-fouling paints.<br>Noise from ships.<br>Maritime transport responsible for about 3 per cent of global greenhouse gas emissions.                                                     |
| Ports [18]                                  | 5.09 billion tons of bulk cargo<br>Competent IGO – IMO and MARPOL convention, but mostly local jurisdiction                                     | Technology development has made consistent dockworker statistics unavailable                                                                                                                        | Concentration of shipping and potential environmental impacts of shipping.<br>Need for dredging and access to deep water passages.<br>Impacts on seabed and coastline from construction of infrastructure.<br>Noise.                                                                                                                                                                                                                                                                                                                                                                            |
| Offshore hydrocarbon industries [21]        | US\$500 billion (at US\$50 per barrel)                                                                                                          | 200,000 workers in offshore production                                                                                                                                                              | Release of hydrocarbons particularly during blowouts or platform disasters, with potential for very large volumes to enter marine systems, with high persistence impacting on tourism and aesthetic and cultural values.<br>Oiling of marine and coastal organisms and habitats.<br>Contaminants entering food webs and potential human food sources<br>Chronic release of chemicals used in operations.<br>Episodic release of dispersants during spill clean-up.<br>Local smothering of benthos.<br>Noise from seismic surveys and shipping.<br>Disturbances of biota during decommissioning. |
| Other marine-based energy industries [2]    | 7.36 MW (megawatts) produced<br>Competent IGO – primarily local jurisdiction                                                                    | 7-11 job-years per MW generated                                                                                                                                                                     | Competition for space for infrastructure and displacement of biota.<br>Localized mortality of benthos due to infrastructure.<br>Mortality of birds, fish in energy turbines and windmills.<br>Noise and physical disturbance during construction and decommissioning of infrastructure.                                                                                                                                                                                                                                                                                                         |
| Marine-based mining [23]                    | US\$5.0-5.4 billion<br>Competent IGO – ISA                                                                                                      | 7,100–12,000 (incomplete)                                                                                                                                                                           | Mortality, displacement or extinction of marine species, particularly benthos.<br>Destruction of seabed habitat, esp. if fragile or sensitive.<br>Creation of sediment plumes and deposition of sediments.<br>Noise.<br>Potential contamination of food chains from deep-sea mining.<br>Creation of microhabitats vulnerable to sediment concentration and anoxia [23.3].                                                                                                                                                                                                                       |
| Marine-based tourism [27]                   | US\$2.3 trillion (35 per cent of coarse estimate of all tourism, including multiplier effects)<br>Competent IGO – none                          | Not estimated due to lack of common treatment of multiplier effects. Overall tourism considered to comprise 3.3 per cent of global workforce, but breakout of marine and not-marine not consistent. | Construction of coastal infrastructure changing habitats, increasing erosion, mortality and displacement of biota, noise.<br>Contamination of coastal waters by waste and sewage.<br>Disturbance of organisms by increased presence of people, especially diving in high-diversity habitats, and watching marine megafauna.<br>Increased mortality due to recreational fishing. Increases boating with all the impacts of shipping on local scales.                                                                                                                                             |

IGO: Intergovernmental organisations; IMO: International Maritime Organization; ISA: International Seabed Authority; MARPOL: the International Convention for the Prevention of Pollution from Ships.

Sources: Unless indicated otherwise, all information is taken from the First Global Integrated Marine Assessment (United Nations 2016), with chapter(s) indicated in first column. For some industries, economic value is recorded so differently by different countries that global economic value cannot be estimated meaningfully, and other indicators of scale of the industry are used. Reporting year also not standardized for all rows, but all estimates are 2012 or later. Table entries should be taken as indicative of global scale with large variation regionally and nationally. IMO (2015).

Developing effective management strategies therefore requires policies that can address cumulative impacts and not just separate sectoral footprints (Halpern *et al.* 2008).

## 7.3 State

### 7.3.1 Coral bleaching crisis 2015-17

Tropical coral reefs<sup>2</sup> are among the most biodiverse ecosystems on earth, hosting approximately 30 per cent of all marine biodiversity (Burke *et al.* 2012). The 'Coral Triangle' region, which includes Indonesia, Malaysia, Philippines, Timor-Leste, Papua New Guinea and Solomon Islands, is the area of greatest biodiversity, hosting more than 550 species of hard corals (c.f. 65 coral species in the Caribbean and Atlantic region). Globally, coral reefs cover an area of around 250,000 km<sup>2</sup>. Due to multiple human pressures, including pollution, fishing and coral bleaching, the current state of reef health is very poor at many sites.

Coral bleaching occurs when corals are stressed by changes in conditions such as temperature, light or nutrients, causing them to expel symbiotic algae living in their tissues, revealing their white skeletons. Large-scale coral reef bleaching events attributed to warmer surface ocean temperatures have been regularly reported over the last two decades and climate research reveals that the recurrence interval between events is now about six years (Hughes *et al.* 2018). The 2015 northern hemisphere and 2015-2016 southern hemisphere summers were the hottest ever recorded and caused the worst coral bleaching on record. The United States National Oceanic and Atmospheric Administration (NOAA) declared 2015 as the beginning of the third global coral bleaching event, following similar events in 1998 and 2010. Still ongoing, this third event is the longest and most damaging recorded, to date affecting 70 per cent of the world's reefs, with some areas experiencing annual bleaching (**Figure 7.2**). Australia's Great Barrier Reef has been particularly hard hit, with more than 50 per cent of the

reef impacted since 2016 (Australia, Great Barrier Reef Marine Park Authority [GBRMPA] 2017).

The severity of bleaching varies both within reefs and between regions, and some areas that have not previously experienced bleaching have been impacted in this latest event. A recent initiative to identify the 50 reef areas most likely to survive beyond the year 2050 has been announced, with the goal of encouraging governments to set these areas aside for protection and conservation (<https://50reefs.org>).

The recently published summary of IPCC Fifth Assessment Report, O'Neill *et al.* (2017) concluded that there "is robust evidence (from recent coral bleaching) of early warning signals that a biophysical regime shift already may be underway". Veron *et al.* (2009) predicted the coral reef bleaching tipping point (an abrupt change in state that occurs when a threshold value is exceeded) would occur once global atmospheric CO<sub>2</sub> reached 350 ppm. This value was reached in about 1988, but because ocean warming lags behind global atmospheric CO<sub>2</sub> levels (Hansen *et al.* 2005) it has taken almost 30 years for the impact of this level of CO<sub>2</sub> to be revealed. The lag effect is due to the slow rate of global ocean circulation compared with the rapid rate of rising CO<sub>2</sub> levels. In effect, the ocean is currently responding to CO<sub>2</sub> levels of decades ago and the balance of evidence indicates that a tipping point for coral bleaching has now been passed (Hoegh-Guldberg *et al.* 2007; Frieler *et al.* 2013). The Veron *et al.* (2009) 350 ppm tipping point, reached 29 years ago, may have been the death sentence for many corals. And given that global atmospheric CO<sub>2</sub> levels are now in excess of 400 ppm, there are serious implications for the very survival of coral reefs. Recent modelling suggests more than 75 per cent of reefs will experience annual severe bleaching before 2070, even if pledges made following the 2015 Paris Climate Change Conference (COP 21) become reality (van Hooidonk *et al.* 2016; UNEP 2017). Experts agree that the coral reefs that survive to the end of the 21<sup>st</sup> century will bear little resemblance to those we are familiar with today (Hughes *et al.* 2017).

**Figure 7.2: Map showing the maximum heat stress during the 2014-17 (still ongoing at the time of writing) period of the global coral bleaching event**

Alert Level 2 heat stress indicates widespread coral bleaching and significant mortality. Level 1 heat stress indicates significant coral bleaching. Lower levels of stress may have caused some bleaching as well.

Source: United States National Oceanic and Atmospheric Administration (NOAA) (2017).

<sup>2</sup> Tropical coral reefs do not include deep, cold-water reefs or temperate rocky reefs.

### 7.3.2 Fisheries

#### Capture fisheries

In addition to changes in ocean status due to natural variation and climate change, people change the state of the ocean by removing resources from it. Most widespread and largest in magnitude is the harvesting of fish and other marine organisms for human consumption and some industrial uses (e.g. feed for aquaculture).

The ocean is an increasingly important source of food (International Labour Organisation [ILO] 2014). Total production from capture fisheries and mariculture<sup>3</sup> exceeded 170 million (metric) tons by 2017 and the mariculture contribution continues to grow (FAO 2018a). Fish provide more than 20 per cent of dietary protein to over 3.1 billion people, with this percentage high in coastal areas where food security concerns are also high. Moreover, the micronutrients in fish are an important contribution to human health, and are difficult to replace in areas where availability of fish is declining (Roos *et al.* 2007; FAO and World Health Organization [WHO] 2014; Thilsted *et al.* 2014).

Capture fisheries have been stable at around 90 million tons for over 15 years, whereas production from culture facilities has continued to increase (**Figure 7.3**). There are debates about the sustainability of present levels of fishing, with disagreements about many fundamental points regarding stock status, causes of trends and effectiveness of management measures (Worm *et al.* 2009; Froese *et al.* 2013; Melnychuk *et al.* 2016). Some fishing crises have become textbook stories of harm from diverse combinations of overexpansion of fishing capacity

and effort, unmanaged technological innovation, politicized or non-precautionary decision-making, and ineffective science, management and governance. In addition, interactions of environmental change and stock dynamics in the face of inertia in management decisions played central roles in the collapse of the cod fisheries in eastern Canada (Rose 2007; Rice 2018), and fisheries for Pacific small pelagic species off Peru and Chile (Chavez *et al.* 2008).

The large volume of literature on fisheries sustainability contains many cases of both unsustainable expansion, and successes in managing exploitation rates and rebuilding previously depleted stocks. For countries where capacity and political will exist to assess stock status and fishing mortality, and implement monitoring, control and surveillance measures, trends from 1990 to the present indicate that overfishing is usually avoided (Hilborn and Ovando 2014; Melnychuk *et al.* 2016). However, the reviews also show wide variation among countries, with factors such as overall wealth to invest in fisheries research and management while avoiding capacity-enhancing subsidies, strongly affecting the ability to keep fisheries sustainable. In the large majority of cases where jurisdictions have resources for sufficient research and management, and have implemented effective governance, fishing mortality has been constrained or reduced to sustainable rates, and stocks are assessed as either healthy or recovering from historical overfishing (**Figure 7.4**). However, where significant funding for resource assessments and monitoring, control and surveillance measures are not made available, overfishing, illegal, unreported or unregulated (IUU)<sup>4</sup> fishing and resource depletion continue and may be expanding.

**Figure 7.3: World capture fisheries and aquaculture production**

Source: FAO (2018a).

<sup>3</sup> For this report 'aquaculture' is a general term used for raising fish and shellfish in captivity for eventual human consumption, whereas 'mariculture' is the portion of aquaculture practised in marine, coastal and estuarine areas.

<sup>4</sup> Illegal, unreported and unregulated (IUU) fishing is a broad term which includes: fishing and fishing-related activities conducted in contravention of national, regional and international laws; non-reporting, misreporting or under-reporting of information on fishing operations and their catches.

**Figure 7.4: Status of fish stocks and fishing mortality as influenced by various factors of science, management and governance. Higher relative scores on vertical axis reflect better stock status relative to theoretically 'ideal' management**

Effects of fisheries management attributes in research (R), management (M), enforcement (E), and socioeconomics (S) dimensions on the current status and trends of biomass (B) and fishing mortality (F). Line thickness reflects the different importance of each dimension on the relationship of the x and y variable.

Source: Melnychuk *et al.* 2016

In addition, fisheries are still expanding geographically, with management jurisdictions scrambling to keep pace. Causes include:

- ❖ effort displaced from jurisdictions trying to reduce exploitation on stocks within their authority,
- ❖ a continued increase in fishing capacity of fleets based in Asia (although fleet capacity of other jurisdictions is decreasing), and
- ❖ overall increases in efficiency of fishing on global scales (Bell, Watson and Ye 2017; Jacobsen, Burgess and Andersen 2017).

Spatial realignment of fishing effort will occur as stocks move in response to changes in ocean conditions due to anthropogenic global warming (Cheung, Watson and Pauly 2013), but the details of species' redistributions is uncertain (Barange *et al.* 2014; Johnson *et al.* 2016; Salinger *et al.* 2016) and management strategies appropriate for such dynamics are in the early stages of development (Schindler and Hilborn 2015; Creighton *et al.* 2016).

Fisheries have expanded to many oceanic seamounts, where accumulated biomass of long-lived, slow-growing fishes, such as orange roughy and oreos, are often depleted even before the regional fisheries management organizations/bodies can collect sufficient information to assess sustainable harvest levels (FAO 2009a; Koslow *et al.* 2016). As fish stocks in polar

### Box 7.1: Fisheries in the polar oceans

The polar oceans were not identified as a GEO-6 Region, but many of the sectors listed in **Table 7.1** are also present in one or both polar regions. Estimates of economic value and livelihoods supported are incomplete, but marine resources remain essential to the livelihoods of over 150,000 Inuit in the North American Arctic (Inuit Circumpolar Council 2011). Commercial fishing in the Arctic Ocean is under moratorium by the United States of America and Canada within their national jurisdictions, and in the international Arctic waters the initial Canada–Russian Federation–United States of America moratorium was recently joined by China, Denmark (for Greenland), the European Union, Iceland, Japan and Republic of Korea.<sup>5</sup> For the polar areas under Norwegian and Russian jurisdiction, fisheries are managed by the national authorities and regularly assessed by the International Council for Exploration of the Seas (ICES).

In the Southern Ocean, commercial fisheries for toothfish, icefish and krill have been prosecuted under Commission for the Conservation of Antarctic Marine Living Resources' (CCAMLR) regulatory framework since 1982. The toothfish and krill fisheries expanded rapidly, with krill catches less than a third of the precautionary catch limit (Commission for the Conservation of Antarctic Marine Living Resources [CCAMLR] 2016). Toothfish and icefish fisheries have been certified as sustainable (by the Marine Stewardship Council, an independent body), with substantial progress in deterring IUU (Österblom and Bodin 2012). The legal fisheries produced annual revenue of over US\$200 million (toothfish) and US\$70 million krill over five years (Hoshino and Jennings 2016). CCAMLR has periodic independent reviews of its performance (e.g. CCAMLR 2016). Polar oceans are experiencing the most rapid climate change and northern livelihoods are being impacted in many detrimental ways (Inuit Circumpolar Council 2011). For example, seasonal access of indigenous fishers to sea-ice fisheries has become problematic as sea ice thins and disappears. Opportunities for mining seabed, hydrocarbon resources and commercial shipping will require development of appropriate policies to ensure any benefits flow to local inhabitants.

latitudes become more available to commercial fisheries through a combination of melting sea ice and improved technologies for harvesting, overfishing could be a particular threat, if not carefully regulated (**Box 7.1**). Such fisheries can expand rapidly, challenging the capabilities of management jurisdictions (Swan and Gréboval 2005), with regional fisheries management organizations/bodies playing a major role as fisheries expand in areas beyond national jurisdiction.

Where overfishing has been reduced or eliminated, or new fisheries have been constrained within sustainable levels, a wide mix of measures have been used (Melnichuk *et al.* 2016; Garcia *et al.* 2018). Efforts to constrain total catches (number and sizes of fishing vessels, days fishing, etc.) are almost universally present and technological innovation is at least monitored if not managed. Where science and management resources allow, the regulatory measures are usually informed by biologically based management reference points and harvest control rules (Inniss and Simcock eds. 2016). However,

top-down management based on scientific assessments and advice is not essential in all types of fisheries. In small-scale community-based fisheries community management is often effective, as long as the coherence with traditional cultural practices is high (FAO 2015). In all scales of fisheries, co-management and inclusiveness of industry participants in management can pay off in greater compliance and lower management costs (Gray 2005; Dichmont *et al.* 2016; Leite and Pita 2016).

Small-scale fisheries have been a cornerstone of livelihoods and food security in many parts of the world for centuries but only recently have been recognized as a major consideration in fisheries status and trends. (FAO 2005; SDG 14.b.a; FAO 2018b). Providing nearly 80 per cent of the employment in fisheries globally (FAO 2016a) they often operate in circumstances where centralized top-down management would be both very expensive and culturally intrusive (FAO 2015; FAO 2016b). After extensive consultation globally, guidelines for the performance

### Box 7.2: Mercury in the marine environment

The World Health Organization places mercury in the top ten chemicals of major public health concern (WHO 2017). This is because mercury, especially in the form of methylmercury, is a powerful neurotoxin, which even at low concentrations can affect fetal and childhood development and cause neurological damage (Karagas *et al.* 2012; Ha *et al.* 2017). Epidemiological studies of elevated prenatal methylmercury exposure in populations from the Faroe Islands and New Zealand have found some adverse developmental impacts (Grandjean *et al.* 1997; Crump *et al.* 1998). However, studies in the Seychelles and the United Kingdom of Great Britain and Northern Ireland found that the regular consumption of ocean fish during pregnancy did not pose a developmental risk (Myers *et al.* 2003; Daniels *et al.* 2004; van Wijngaarden *et al.* 2017). Further research on the United Kingdom cohort found that seafood intake during pregnancy (>340 g per week) improved developmental, behavioural and cognitive outcomes (Hibbeln *et al.* 2007), suggesting other nutrients present in fish such as long-chain polyunsaturated fatty acids (Strain *et al.* 2008) or selenium (Ralston and Raymond 2010) may obscure or counteract the negative effects of the methylmercury.

The health benefits of eating fish are well established (FAO and WHO 2011; FAO and WHO 2014); however, due to high methylmercury levels in some seafood and the uncertainty regarding risk, many countries have advisories suggesting that pregnant women should limit their intake of fish to species that record low concentrations of mercury (Taylor *et al.* 2018). Generally, the fish to be avoided are predatory species such as shark, tuna and swordfish and long-lived fish such as orange roughy due to the processes of biomagnification and bioaccumulation (United States Food and Drug Administration 2017).

<sup>5</sup> 2017 Agreement to Prevent Unregulated High Seas Fisheries in the Central Arctic Ocean.

Figure 7.5: Biomagnification and bioaccumulation of methylmercury in the food chain

Source: Baker, Thygesen and Roche (2017).

and governance of small-scale fisheries are already leading to improvements in these fisheries (FAO 2015; FAO 2016b).

### Emergence of mariculture

Although capture fisheries plateaued in the early 2000s, mariculture continues to expand and, if current trends continue, will soon surpass them (Figure 7.4; FAO 2018a). Large-scale mariculture of market-oriented, high-value fish and shellfish such as tuna, salmon, mussels, oysters and other bivalves, now contributes significantly to the economies of most coastal developed countries. Small-scale mariculture is also expanding through less-developed countries and economies in transition. Freshwater and marine culture which use fish-processing by-products and low-value fish as feed, create both new markets for low-value fisheries products and some potential for market competition as mariculture demand for feedstocks increases. Data on production from small-scale operations are incomplete, especially for community consumption, as these products do not enter the market.

Populations reliant on marine organisms for nutrition may have particularly high exposures to methylmercury and persistent organic pollutants and these risks are highest in areas where food security is not assured (Gribble *et al.* 2016).

In addition, climate change may lead to changes in emissions of mercury, for instance through its release from long-term storage in the frozen peatlands of the northern hemisphere (UNEP 2013; Schuster *et al.* 2018). This has the potential to increase input of mercury into the oceans.

### 7.3.3 Marine litter

Marine litter is a growing problem, that has serious impacts on marine organisms, habitats and ecosystems (Secretariat of the Convention on Biological Diversity [SCBD] 2016). Litter has been found at all ocean depths and on the ocean floor (Pham *et al.* 2014) and on the shores of even the most remote Pacific islands (Lavers and Bond 2017). Three-quarters of all marine

litter is composed of plastic. This includes microplastics of less than 5 mm in size, which are either purposefully manufactured (primary microplastics) for use in various industrial and commercial products (e.g. pellets, microbeads in cosmetics), or are the result of weathering of plastic products and synthetic fibres that can produce micro- and nanoplastic particles (Joint Group of Experts on the Scientific Aspects of Marine Environmental Protection [GESAMP] 2015; Gigault *et al.* 2016). Weathering can also release the chemical additives that are used in plastic manufacture (Jahnke *et al.* 2017).

Based on global solid waste data, population density and economic status, Jambeck *et al.* (2015) estimate that 275 million tons of plastic waste were generated in 192 coastal countries in 2010, of which 4.8 to 12.7 (8) million tons may have washed into the ocean (Figure 7.6). They calculate that without global intervention, the quantity of plastic in the ocean could increase to 100-250 million tons by 2025. Sources of marine litter can generally be correlated with the efficiency of solid waste management and wastewater treatment (Schmidt *et al.* 2017).

It is generally accepted that a large proportion of the plastic entering the ocean originates on land. It makes its way into the marine environment via storm water run-off, rivers or is directly discharged into coastal waters (Cozar *et al.* 2014; Wang *et al.* 2016). Uncollected waste is thought to be the major source, with lesser amounts coming from collected waste re-entering the system from poorly operated or located formal and informal dumpsites (see 5.2.5). There is less information on the percentage of plastic coming from ocean-based sources, but we do know that lost fishing gear is a problem. This includes gear that is lost as a result of fishing method, washed overboard during storms or is intentionally discarded (Macfadyen, Huntington and Cappell 2009).

## 7.4 Impacts

### 7.4.1 Social and economic consequences of death of coral reefs

Coral reefs are of major importance for 275 million people located in 79 countries who depend on reef-associated fisheries as their major source of animal protein (Wilkinson *et al.* 2016). The contributions provided by coral reefs have collectively been valued at US\$29 billion per annum, in the form of tourism (US\$11.5 billion), fisheries (US\$6.5 billion) and coastal protection (US\$10.7 billion) (Burke *et al.* 2012). Bleaching of corals in the Great Barrier Reef alone could cost the Australian economy US\$1 billion pa in lost tourism revenue (Willacy 2016). The total annual economic value of coral reefs in the United States of America has been valued at US\$3.4 billion (Brander and Van Beukering 2013).

Coral reefs that have been degraded by the compounding effects of pollution from land or repeated bleaching events, are less able to provide the benefits on which local communities depend (Cinner *et al.* 2016). Once corals have died, they no longer grow vertically upwards, so the reefs gradually erode. Dead reefs become submerged under rising sea level and are less effective in providing shoreline protection from wave attack during storms. Dead corals not only lack the aesthetic appeal that is fundamental to reef tourism, they also sustain a less biodiverse fish community (Jones *et al.* 2004). This results in reduced tourist activity and reduced income from fisheries, which can threaten the livelihoods of local communities. Living coral reefs are also important religious symbols for some communities (Wilkinson *et al.* 2016).

**Figure 7.6: Global map of potential marine plastic input to the oceans based on human activities and watershed characteristics**

Source: Map produced by GRID-Arendal (2016a) based on data from Halpern *et al.* (2008), Watson *et al.* (2012) and Jambeck *et al.* (2015).

### 7.4.2 Capture fisheries

The initial impact of fishing on the target species is to reduce abundance from the unfished level. This reduction, in turn, is expected to produce increases in population productivity as density-dependence pressures are reduced, so both growth and energy reserves are available for spawning increase. This reasoning underpins basic fisheries science (Beverton and Holt 1957; Ricker 1975) and the concept of a Maximum Sustainable Yield (MSY) is entrenched in the United Nations Convention on the Law of the Sea (UNCLOS). This concept is a global norm for fisheries management, when the rate of removals by fisheries has maximized productivity without depleting the size of the spawning population sufficiently to impair production of recruits. If the exploitation rate increases beyond this level, spawning potential is diminished faster than productivity is enhanced, and overfishing occurs. The current global outcomes of fishing on target species were summarized in Section 7.3.2.

The impacts of fishing on marine ecosystems are well documented and have been studied for several decades (Jennings and Kaiser 1998; Gislason and Sinclair 2000). Major impacts include:

- ❖ by-catches of non-target species in fishing operations
- ❖ impacts of fishing gear on seabed habitats and sedentary benthic communities
- ❖ alteration of food webs through reduction in abundance of either top predators potentially allowing release of prey populations, or depletion of prey populations leading to decreased productivity of predator populations.

The pathways of these impacts are well described, and have been central in the development of the ecosystem approach to fisheries. This was entrenched in the United Nations Fish Stocks Agreement and has been widely adopted in national

and regional policies (Rice 2014). FAO has provided operational guidance on actions to manage fisheries' footprint (FAO 2003) and updates, and it has been taken into the Code of Conduct on Responsible Fishing (FAO 2005; FAO 2011).

Despite acknowledgement of fisheries' large footprint on marine ecosystems, and the full uptake in policy, measures to minimize the ecosystem effects of fishing have had mixed success. There appears to be overall progress, as two global reviews a decade apart found estimates of global annual discards from fisheries to have declined from 27 million tons in 1994 to 7.3 million tons in 2004 (Alverson *et al.* 1994; Kelleher 2005). However, substantial discarding remains in many fisheries, particularly small mesh fisheries for species such as shrimp in less-developed countries, where incentives for reduction of discards and by-catch are absent or ineffective (FAO 2016a; FAO 2016b). Moreover, even where by-catches of highly vulnerable species have been reduced, levels still present population concerns for some sharks and seabirds (Campana 2016; Northridge *et al.* 2017).

Similarly, the footprint of fishing gear on sea floor habitat and benthic communities is being taken seriously by fisheries management organizations at national and regional scales. This concern has increased, prompting the adoption in the United Nations General Assembly of Resolution 61/105 in 2007, which required all regional fisheries management organizations (RFMOs) to identify marine ecosystems in their jurisdiction that would be vulnerable to bottom-contacting gear and to either protect them from harm or close them to such fishing. The evidence for policy effectiveness of this approach is examined in Chapter 14. However, despite all relevant RFMOs acting to comply with this requirement (Rice 2014), regional studies find that well over 50 per cent of fishable seabed has been impacted by fishing gear more often than benthic communities can recover fully from the disturbance, and repeated impacts remain common (Eigaard *et al.* 2017).

### 7.4.3 Mariculture

Mariculture has a substantial impact on the marine ecosystem, and documentation of these effects is growing. Conversion of mangroves for mariculture has resulted in widespread habitat loss with far-reaching implications for dependent species. In open, dense culture facilities, antibiotics and other medications used to prevent disease are carried by currents and tides well outside the waters in the culture area. Excessive feed sinking through the cages can accumulate on the sea floor, decompose and reduce oxygen levels. These and other effects, such as being vectors or resources for parasites and diseases, or increasing risks of non-adaptive gene-flow and invasive species, can be managed through careful, albeit sometimes costly operations (Bernal and Oliva 2016). However, the ecosystem approach is also being applied in aquaculture, with comparable objectives and rapid uptake by industry (FAO 2010).

### 7.4.4 Marine litter

Although the greatest accumulation of marine litter is in coastal environments (Derraik 2002), plastic (including microplastic) is distributed worldwide in the ocean, with increased accumulation in the convergence zones of each of the five subtropical gyres (Cozar *et al.* 2014; Van Sebille *et al.* 2015; Yang *et al.* 2015; see **Figure 7.7**).

Plastic pollution has been recognized for decades as a threat to marine biodiversity (Gray 1997). One of the most visible impacts is death or injury of marine life from entanglement with derelict fishing gear and plastic packaging. Many animals also ingest litter, either accidentally or intentionally when it is mistaken for food. This can cause starvation due to intestinal blockage or lack of nutrition (UNEP and GRID-Arendal 2016). Recent reviews have found that a growing number of turtles, marine mammals and seabirds are endangered or killed by floating litter (Thiel *et al.* 2018; O'Hanlon *et al.* 2017).

**Figure 7.7: Plastic litter in the open ocean**

Source: GRID-Arendal (2016b), based on data from Van Sebille *et al.* (2015)

Microplastics are now appearing in food consumed by humans; however, the impact on human health is uncertain (GESAMP 2015; Halden 2015). Plastic particles have been found in the intestines of fish from all oceans and in products such as sea salt (e.g. Yang *et al.* 2015; Güven *et al.* 2017). There are currently no standard methods for assessing the health risks of ingesting plastic particles. For fish at least, people do not generally consume their digestive tract where plastic accumulates, so intake is probably limited. In instances where people consume whole organisms, such as mussels and oysters, ingestion rates could be higher (Van Cauwenberghe and Janssen 2014; Li *et al.*, 2018). Moreover, the aesthetic and restorative value of the ocean for people is well known, but there is evidence that the presence of marine litter can undermine the psychological benefits generally provided (Wyles *et al.* 2015).

Some plastic products contain dangerous chemicals (e.g. fire retardants) and plastic marine litter can also attract chemicals from the surrounding seawater (e.g. UNEP 2016; UNEP and GRID-Arendal 2016). However, the fraction of chemicals contained in plastic or sorbed to plastic in the ocean, is currently considered to be small compared to the chemicals found in seawater and organic particles that originate from other land-based sources of pollution (Koelmans *et al.* 2016). There are currently no proven toxic effects of chemicals

sorbed by plastic particles found across a range of marine biota, but more data are needed to fully understand the relative importance of exposure to sorbed chemicals from microplastics compared with other exposure pathways (Ziccardi *et al.* 2016).

The economic and social costs of marine litter include indirect effects such as interfering with small-scale fishing opportunities, tourism and recreation (Watkins *et al.* 2017). These costs are generally unquantified but may fall disproportionately on those with livelihoods most closely tied to coastal activities. Some direct economic costs include the cost of beach cleanup and accidents related to navigation hazards or fouling (UNEP 2016). The European Union has estimated that every year up to €62 million are lost to the fishing industry from damage to vessels and gear and reduced catch due to ghost fishing (abandoned gear that continues to catch marine organisms as it drifts) and up to €630 million is spent on beach cleaning (Acoleyen *et al.* 2013).

#### 7.4.5 Emerging Issues for the Ocean

Exploitation of the ocean is expanding and a number of key emerging issues will need to be addressed by policy makers as this exploitation continues.

#### Box 7.3: Coastal sand mining

Around the globe, coastal and nearshore areas are being mined for construction sand and gravel. These are non-renewable resources, although deposits are replenished by a number of processes including erosion of the coast, riverine transport of sediments and biological production (Woodroffe *et al.* 2016) and landward sediment transport. Sand and gravel are the second most-used natural resource on our planet, after water. Annual sand and gravel consumption is estimated at around 40-50 billion tons (5.2-6.6 tons per person per year, or c.20 kg per person per day), 26 billion tons of which is used for making concrete (Peduzzi 2014).

Most sand comes from the erosion of mountains by rivers and glaciers. It is estimated that all the Earth's rivers deliver around 12.6 billion tons of sediment to the sea each year (Syvitski *et al.* 2005). Consequently, humans are currently using sand at a rate four-times that at which it is being produced by nature. Desert sand cannot be used as an aggregate because the grains are too smooth and rounded from constant motion over desert dunes.

Many European countries have been mining sand from offshore sand banks for several decades (Baker *et al.* 2016). The practice is expanding rapidly in other parts of the world, but the exact volume mined is currently uncertain. The act of dredging the seabed kills organisms in the mined area and the plume of disturbed mud can blanket the seabed and smother sea life in surrounding areas. Illegal and poorly regulated sand mining on beaches (and in rivers) is causing major damage to ecosystems and landscapes (Larson 2018). For example, in Kiribati, beach mining has increased vulnerability to coastal inundation (Ellison 2018) and in central Indonesia, sand mining is one of the identified threats to seagrass beds (Unsworth *et al.* 2018).

Actions to reduce the global 'sand mining footprint' include conserving existing buildings and substituting recycled material for sand and gravel in new projects. It is also possible to replace sand in concrete with 15-70 per cent of incinerator ash, depending on the use (Rosenberg 2010). Research into developing desert-sand-based concrete is expanding and new products are currently being trialled (Material District 2018).

Improved knowledge of sandy environments and their dependent ecosystems is needed in order to make the wisest use of remaining sand and gravel resources (Peduzzi 2014). There is no mention of seabed mining or coastal erosion in the SDG indicators.

#### Box 7.4: Deep sea mining

Commercial deep sea mining has not yet begun, but the International Seabed Authority (ISA) has currently entered into 15-year contracts with companies for exploration of polymetallic nodules (the Clarion Clipperton Fracture Zone and the Central Indian Basin), polymetallic sulphides (South West Indian Ridge, Central Indian Ridge and the Mid-Atlantic Ridge) and cobalt-rich ferromanganese crusts (Western Pacific Ocean). In addition, a number of Pacific Island nations with potential deep sea mineral resources have issued exploration licences or are updating relevant policies before doing so.

Globally, deep sea mineral deposits are becoming more attractive to mining companies as they search for higher grade ore bodies (Secretariat of the Pacific Community [SPC] 2013a; SPC 2013b). These include: (1) manganese nodules that exist as cobble- to boulder-sized rocks scattered over broad areas of the abyssal ocean floor at depths exceeding 5,000 m; (2) cobalt-rich crusts formed on the flanks of seamounts and other volcanic sea floor features; and (3) massive sulphide deposits that are formed in association with hydrothermal vents found along sea floor spreading ridges, back arc-basins and submarine volcanic arcs. Benthic communities inhabiting these environments are globally unique and host many endemic species (Beaudoin and Smith 2012). Interest in mining these deposits is most advanced in relation to massive sulphide deposits located in the south-west Pacific, but many unanswered questions remain about the environmental impacts (Boschen *et al.* 2013).

Potential impacts of deep sea mining are poorly studied, but are generally assumed to include (1) direct impacts on the benthic communities where nodules/ore deposits are removed; (2) impacts on the benthos due to mobilization, transport and redeposition of sediment over potentially broad areas; and (3) impacts in the water column in cases where mining vessels discharge a plume of sediment near the sea surface, thus affecting photosynthesizing biota and pelagic fish (Morgan, Odunton and Jones 1999; Sharma 2001). A seabed disturbance experiment in the Peru Basin found very little recovery of benthic fauna 26 years after mimicking mining operations (Marcon *et al.* 2016). Lack of knowledge and understanding has been argued as one reason for countries to proceed with caution in developing these resources (Van Dover 2011; Van Dover *et al.* 2017). In the context of deep sea mining, the world has a unique opportunity to make wise decisions about an industry before it has started.

The ISA is responsible for ensuring effective protection of the marine environment from harmful effects of deep sea mining in areas beyond national jurisdiction (in accordance with Part XI of the United Nations Convention on the Law of the Sea). The Authority is in the process of developing the Mining Code, which contains rules, regulations and procedures to regulate prospecting, exploration and exploitation of marine minerals in the area (International Seabed Authority [ISA] 2017).

Many states with potential deep sea minerals have developed or are developing policies to regulate this new industry. These include a range of initiatives – for example, the Secretariat of the Pacific Community Regional Legislative and Regulatory Framework for Deep Sea Minerals Exploration and Exploitation (SPC 2013b), Cook Islands National Seabed Minerals Policy (Cook Islands Seabed Minerals Authority 2014) and the Tuvalu Seabed Mining Act 2014 (Tuvalu 2014).

#### Box 7.5: Anthropogenic ocean noise

There is increasing concern regarding the potential impact of anthropogenic acoustic noise on marine life. This is noise generated by a range of activities including shipping, seismic surveys, military operations, wind farms, channel dredging and aggregate extraction (Inger *et al.* 2009). Large commercial ships generate noise in the frequency range from 10 to 1,000 Hz, which coincides with frequencies used by marine mammals for communication and navigation (Richardson *et al.* 1995). There is evidence that low-frequency noise has increased significantly in the deep ocean since the 1950s (Andrew *et al.* 2002; McDonald *et al.* 2006; Chapman and Price 2011). However, some recent observations have shown a constant level or slightly decreasing trend in low-frequency noise (Andrew *et al.* 2011; Miksis-Olds and Nichols 2016). There is limited information on noise levels in the shallower water of the continental shelf (Harris *et al.* 2016).

Evolutionary adaptations that have allowed many marine species to detect sound may now make them vulnerable to noise pollution (Popper and Hastings 2009). Sound energy dissipates as a function of the distance squared, so proximity to the sound source is a major factor for calculating impact. Early research on noise and marine mammals focused on high-frequency sound, such as ship sonar, which had been implicated in whale strandings (e.g. Fernández *et al.* 2005). More recently, researchers have tried to determine the impacts of common, low-frequency sounds on marine mammals. Although it is difficult to determine the impact of anthropogenic noise on marine mammals, there is general consensus that it can cause adverse effects, from behavioural changes to strandings (Götz *et al.* 2009). A review by Cox *et al.* (2016) on the impact of ocean noise on fish behaviour and physiology determined that certain sounds can disrupt communication and interfere with predator-prey interactions. Low-frequency noise has also been found to impact crustaceans, producing changes in behaviour and ecological function (Tidau and Briffa 2016).

There are increasing concerns about the long-term and cumulative effects of noise on marine biodiversity (CBD 2012). The CBD (operational paragraph 3 of Decision XIII/10) calls for improved assessment of noise levels in the ocean, further research, development and transfer of technologies and capacity-building and mitigation (CBD 2016). The European Union Marine Strategy Framework Directive 2017/848 (European Commission 2017) has recently provided criteria and methodological standards to ensure that introduced noise does not adversely affect the marine environment and proposed standardized methods for monitoring and assessment.

The United Nations Convention on the Law of the Sea makes no specific mention of anthropogenic noise, but if the introduction of noise into the marine environment is likely to have a negative impact on the environment, it may be considered a form of pollution under UNCLOS. Delegates at the United Nations Open-ended Informal Consultative Process on Oceans and the Law of the Sea (ICP-19, 2018) discussed recognizing underwater noise as a form of transboundary pollution to be mitigated and addressed through an United Nations General Assembly resolution.

## 7.5 Response

Governance approaches and policy instruments that address impacts on the marine environment are quite varied. General discussion of these policy approaches is provided here while the effectiveness of specific examples is explored in Chapter 14 (Part B).

### 7.5.1 Coral reefs

Since the increased frequency of coral bleaching is attributed to global anthropogenic climate change, only a global policy response can address the root cause of the problem. The term 'coral reefs' is not mentioned in the SDG indicators, including SDG 14 "Conserve and sustainably use the oceans, seas and marine resources for sustainable development". Aichi Target 10 is related to coral reefs conservation: "By 2015, the multiple anthropogenic pressures on coral reefs, and other vulnerable ecosystems impacted by climate change or ocean acidification are minimized, so as to maintain their integrity and functioning." The oceans SDG target 14.2 – "by 2020, sustainably manage and protect marine and coastal ecosystems to avoid significant adverse impacts, including by strengthening their resilience, and take action for their restoration in order to achieve healthy and productive oceans" – may not be attainable for most tropical coral reef ecosystems. The resilience of coral reefs is affected by cumulative human impacts (e.g. fishing, coastal pollution, sediment run-off, invasive species), hence these impacts must be curbed to sustain reefs into the future.

Nations dependent upon reef-based fisheries, tourism and other sectors will need to develop policies for a transition to post-reef economies within the next decade, including dealing with associated cultural trauma, especially in cases where reef degradation is most rapid and spatially widespread. In addition, low-lying coral atoll countries will need to develop policies for a transition to environments where the natural benefits of coral reefs to people are much reduced or no longer available. Given that some reef habitat may be in locations where the impacts of climate change will be less severe, and where corals might survive, reef-owning nations should consider taking immediate action to protect all known coral reef habitat from any non-subsistence uses (i.e. establish all reefs as total no-take, no-go conservation zones) until such time as the location of reefs that are most likely to survive becomes known (Beyer *et al.* 2018). Studies show that where 'no-take' MPAs have been established, reef ecosystem resilience is improved (Steneck *et al.* 2018).

The challenge is to evolve from local management and monitoring towards the multiscale governance of addressing drivers, thresholds and feedbacks at relevant scales. Coral reef management must adapt to embrace new approaches such as resilience and ecosystem-based management, including the manipulation of ecosystems, bio-engineering of heat-resistant coral species as well as building new international institutions and partnerships to tackle the global aspects of the decline in coral reefs (Hughes *et al.* 2017).

### 7.5.2 Fishing

#### **Policies and measures to manage fisheries impacts on ecosystems**

The impacts of fisheries on species not delivered to markets (collectively called by-catch) on the sea floor and its biota, and on marine ecosystem structure and function, have been studied since before the 1980s. Measures to manage all these types of impacts are known and feasible, and can keep them within safe ecological limits (FAO 2009a). These include technologies and practices that make fishing gear more selective for target species, discourage by-catches of marine birds, mammals and reptiles, and avoid or reduce impacts of fishing gear on the sea floor (FAO 2009a; FAO 2009b). Guidance on how, and under what conditions, to apply all these measures has been available for well over a decade (FAO 2003), and has been expanded and updated regularly (e.g. FAO and World Bank 2015). Significant global policy commitments have been made to avoid or mitigate such ecosystem effects of fishing (Rice 2014).

Spatial measures have had a role in fisheries management for over a century and the growing establishment of marine protected areas (MPAs) has accelerated the interest in spatial management approaches. Many ecological and governance factors appear to influence the effectiveness of MPAs and their incremental value to other measures (Rice *et al.* 2012). Overall there is growing awareness that they can help to keep fisheries sustainable, particularly with regard to protection of sensitive habitat features or contributing to improving the status of fish stocks when conventional fisheries management measures are not being implemented effectively. However, MPAs also have a wide range of social and economic impacts that need to be considered on a case-by-case basis (FAO 2007). In addition, conflicting results are found with regard to MPA benefits such as 'spillover effects', and studies of their impacts on coastal livelihoods and implications for food security have produced mixed results (FAO 2016b).

Fisheries are being impacted by climate change in many ways, well documented in IPCC's Fifth Assessment Report, Working Group I (IPCC 2013), and the subject of an upcoming IPCC special report on oceans and cryosphere, expected late in 2019. As temperature and salinity profiles change with global warming, the distribution and productivity of important target species is already being reflected in changes in distribution of fishery catches. Moreover, environmental changes are impacting stock productivity of fish and making them available at different places and/or at different times of the year, with impacts on large-scale mobile fisheries (which may have to fish in different places or at different times) and small-scale fisheries with lower mobility (which may have to adapt to changing species available for harvest). Depending on the cultural practices associated with fishing, these challenges may be disruptive to address.

Ocean acidification is a potential threat to many species, particularly in early life stages, including many shellfish, as calcium carbonate for shell formation is less available in seawater of higher acidity. Estimates of losses from ocean acidification are highly variable, but some projections suggest losses over US\$100 billion by 2100 (Narita, Redhans and Tol 2012; Lemasson *et al.* 2017). Acidification is considered a particularly serious threat in polar areas (Tarling *et al.* 2016), and should be an important consideration.

### Box 7.6: Examples of existing global policy commitments to sustainable fisheries using an ecosystem approach (dates of agreements in brackets)

United Nations Convention on the Law of the Sea Articles 61(4) and 119(1) both make explicit reference to sustainability of associated and dependent species, and many articles in parts V, VI and VII refer to sustainable fisheries [1982].

United Nations Fish Stocks Agreement Article 5.3.d: Develop data-collection and research programmes to assess the impact of fishing on non-target and associated or dependent species and their environment, and adopt plans necessary to ensure the conservation of such species and to protect habitats of special concern [1995].

Aichi Target 6: By 2020, all fish and invertebrate stocks and aquatic plants are managed and harvested sustainably, legally and applying ecosystem-based approaches, so that overfishing is avoided; recovery plans and measures are in place for all depleted species; fisheries have no significant adverse impacts on threatened species and vulnerable ecosystems; and the impacts of fisheries on stocks, species and ecosystems are within safe ecological limits [2010].

United Nations General Assembly 61/105 Paragraph 80: Calls upon states to take action immediately, individually and through regional fisheries management organizations and arrangements, and – consistent with the precautionary approach and ecosystem approaches – to sustainably manage fish stocks and protect vulnerable marine ecosystems, including seamounts, hydrothermal vents and cold-water corals, from destructive fishing practices, recognizing the immense importance and value of deep sea ecosystems and the biodiversity they contain [2006]. This resolution has been followed by several updates.

SDG Target 14.4: By 2020, effectively regulate harvesting and end over-fishing, illegal, unreported and unregulated fishing and destructive fishing practices and implement science-based management plans, in order to restore fish stocks in the shortest time feasible, at least to levels that can produce maximum sustainable yield as determined by their biological characteristics [2016].

#### Social and economic benefits of fishing

The benefits and opportunities for development presented by fisheries is important to different large-scale and small-scale fisheries (LSF and SSF). Some SSF have severely depleted the stocks they exploit, as have some LSF, and some of the most destructive fishing practices, including fishing with dynamite and poisons, are restricted to SSF. The geographic scale of LSF means that even modest by-catch rates or habitat impacts of fishing gear can result in substantial pressure on species taken as by-catch and seabed features (FAO 2009a; FAO 2018a).

SSF and LSF differ in the magnitude of the market value of their catches, and in the employment created, livelihoods supported and social distribution of the benefits provided from fishing. As a generalization with occasional exceptions, LSF provide greater direct economic revenues, but also require much greater capital investment in fishing vessels, gear and processing capacity. On the other hand, employment for the same volume of catch is usually much greater in SSF, especially since significant additional jobs are created in shore-based small-scale market and processing, with sometimes multiple layers of these secondary employment opportunities. These multiplication factors also apply to LSF, which can create substantial coastal employment in

rural areas, but data are rarely collected systematically, so total employment created in all types of fisheries is probably underestimated.

Gender roles also differ between LSF and SSF. Most open ocean fishers are men. Women generally fish on shallow reefs and tidal flats, and in mangroves and coastal estuaries (Lambeth *et al.* 2014). Women often predominate in the post-harvest processing, marketing and trading of fish. These roles are often omitted from data-collection efforts, and overlooked in conventional government or aid programmes that support fishing and fishers (Siason *et al.* 2010). However, when all of the industry workforce is counted, women make up nearly 50 per cent (World Bank 2012; **Table 7.2**).

These issues of magnitude and distribution of revenue and employment created by LSF and SSF present complex choices to policymakers. In developing countries, SSF potentially contribute substantially to development and equitable distribution of livelihoods from fishing. This does not mean that earnings from fishing alone are sufficient to sustain households at a level above the poverty line or above a country's minimum wage (FAO 2016a), and these fisheries are particularly vulnerable to outside threats from factors such as climate

**Table 7.2: Global capture fisheries employment**

|                                        | Small-scale fisheries |        |       | Large-scale fisheries |        |       | Total |
|----------------------------------------|-----------------------|--------|-------|-----------------------|--------|-------|-------|
|                                        | Marine                | Inland | Total | Marine                | Inland | Total |       |
| Number of fishers (millions)           | 13                    | 18     | 31    | 2                     | 1      | 3     | 34    |
| Number of post-harvest jobs (millions) | 37                    | 38     | 75    | 7                     | 0.5    | 7.5   | 82.5  |
| Total                                  | 50                    | 56     | 106   | 9                     | 1.5    | 10.5  | 116.5 |
| Percentage of women                    | 36%                   | 54%    | 46%   | 66%                   | 28%    | 62%   | 47%   |

Source: World Bank (2012).

change (Barange *et al.* 2014; Guillotreau, Campling and Robinson 2012). LSF have greater opportunity to generate revenues for participants and governments (World Bank 2012), but are at greater risk of concentrating the wealth and opportunity generated among a small number of individuals (Olson 2011). How available fish harvests are distributed between SSF and LSF consequently has major consequences for development, employment and revenue generation, which need to be considered fully in any comprehensive fisheries policies.

### **Fisheries and SDGs and the Aichi Targets**

Fisheries have important roles in meeting both SDGs 1 and 2 (end poverty and hunger) as well as SDG 14 (conserve and sustainably use the ocean and its resources). To meet global food security needs, dietary protein from marine sources will have to increase by 50 per cent and likely much more (Rice and Garcia 2011). Some combination of innovative harvest strategies that increase harvest of food sources with presently low market value and ensure their distribution to appropriate markets (e.g. Garcia *et al.* (2012) and expansion of mariculture production will be essential to meeting SDG 2, and can contribute to improving employment and livelihoods supported by production of marine food (SDG 1). These needs pose challenges for SDG 14, as plans for advancing this goal usually involve discussions of reducing the pressure from fisheries on marine ecosystems, rebuilding depleted stocks, ending over- and IUU fishing, and greatly expanding the coverage of no-take MPAs. These goals can be pursued in unison, but only if planning for expanded catches and mariculture production, including its offshore expansion, is done very carefully, with full ecosystem impacts considered in each case. If the 'conserved' part of SDG 14 is interpreted as complementary with 'sustainably used', systems altered from their pristine state are considered 'conserved' as long as major structural properties and functional processes are not altered beyond safe ecological limits as specified in Aichi Target 6. Such careful planning for expansion of food production from the sea could also contribute to SDGs 3 (health and well-being), 5 (gender equity) and 12 (sustainable consumption and production patterns), as long as these factors are part of the benefits sought from the increased food production.

Aichi Target 6 also focuses directly on fishing. In much more detail than SDG 14, it spells out all the ecological factors related to fishing that need to be made sustainable by 2020, including catch levels of all stocks, commitments to rebuilding depleted stocks, management of by-catches and habitat impacts of fishing gear, and establishing resilient ecosystem structure and function.

### **7.5.3 Marine litter**

Policy responses to marine plastics are growing and range from global instruments such as MARPOL, UNCLOS and the Honolulu Commitment and Strategy, through regional action plans such as the Regional Plan on Marine Litter Management in the Mediterranean (UNEP/MAP 2015), and specific product bans (e.g. single-use plastic bags) at municipal or national levels. Marine litter has been incorporated into SDG target 14.1 indicator 14.1.1 as a composite indicator that includes (i) the index of coastal eutrophication and (ii) floating plastic litter density. The third United Nations Assembly (UNEA-3) adopted

resolution UNEP/EA.3/Res.7 which includes the establishment of an open-ended ad hoc expert group to further examine the barriers to and options for combating marine plastic litter and microplastics from all sources, especially land-based sources (UNEA 2017). The first meeting of the expert group was held in Nairobi, Kenya from 29 to 31 May 2018.

Cleaning up coasts and beaches can provide environmental and economic benefits (e.g. Orange County California estimated an economic benefit of more than US\$140 million could be generated annually from the increased number of visitors attracted to cleaner beaches (Leggett *et al.* 2014). However, cleaning up the open ocean does not currently appear to be a practical solution to marine litter. The cost of the ship-time alone needed to clean the litter concentrated in 1 per cent (approximately one million km<sup>2</sup>) of the Central Pacific Gyre is estimated to be between US\$122 million and US\$489 million (NOAA Office of Response and Restoration 2012). Large-scale booms may be effective at trapping surface litter in small areas. The trail of a 600 m long boom by the NGO Ocean Cleanup recently began offshore California. If successful, the boom will be deployed in the open ocean of the North Pacific gyre (Stokstad 2018).

Research suggests that up to 95 per cent of the plastic entering the ocean does not remain in the surface waters (Eriksen *et al.* 2014). However, there is a major knowledge gap in understanding the behaviour and breakdown of plastic in the ocean and where it eventually ends up (Cozar *et al.* 2014). Therefore, efforts to address marine litter should focus primarily on its prevention at source through sustainable consumption and production patterns, sound waste management, wastewater treatment and resource recovery using the principles of a circular economy (Eriksen *et al.* 2014; UNEP 2016).

## **7.6 Conclusions**

The oceans are impacted by numerous human activities and the most serious impacts are related to climate change, land-based pollution and fishing. Within the impacts of climate change, our assessment has mentioned several issues: ocean acidification; sea level rise; changes to bottom water formation; the distribution of many fish and invertebrate species; and ocean circulation. The most dramatic and immediate impact of climate change on the oceans in recent years (GEO-6 cycle) is the bleaching and death of coral reefs. Pollution, particularly from plastic, is a major concern for many marine and coastal ecosystems. In relation to the fisheries sector, the chapter highlights concerns of overfishing, climate change impacts on species distribution patterns and the rise of aquaculture. We therefore summarize some key findings:

1. Tropical coral reefs have passed a tipping point whereby chronic bleaching has killed many reefs that are unlikely to recover even over centuries-long timescales. Reef death will be followed by loss of fisheries, tourism livelihoods and habitats. The demise of tropical coral reef ecosystems will be a disaster for many dependent communities and industries. Even if reef-owning nations take immediate action to protect their coral reefs from non-subsistence uses, there is a major risk that many reef-based industries will collapse over the next decade.

2. Marine litter has been found across all oceans and at all depths. Micro- and nano-plastics are now documented in the food web, including in seafoods consumed by humans. Marine litter has increased, with an estimated 8 million tons per year of plastics entering the ocean, mainly from land-based sources. If nations do not take action to prevent litter from entering the ocean, it will continue to accumulate and compromise ecosystem health and human food security. Prevention involves ensuring recovery and recycling of all used plastic products, encouraging communities to reduce the volume of rubbish generated, and improving solid waste management and wastewater treatment. Cleaning up the oceans is not a sustainable option without action to stop litter from entering the oceans.
3. To meet future challenges of food security and healthy populations, in addition to using all natural products harvested for food more efficiently, more fish, invertebrates and marine plants will have to be taken as food from the oceans and coasts, so both capture fisheries and mariculture must expand while preserving sustainability. It is possible to keep capture fisheries sustainable, but this requires significant investments in monitoring, assessment and management (at national, regional and international levels) and/or strong local community-based approaches. Sustainable mariculture requires knowledge and care in management of operations. Without sound bases in knowledge and governance of fisheries and mariculture, patterns of overexploitation, environmental damage and resource depletion are likely, and neither food security nor health goals will be met.

# Chapter 8

## Land and Soil

**Coordinating Lead Authors:** Nicolai Dronin (Moscow State University), Andres Guhl (Universidad de los Andes), Jia Gensuo (Chinese Academy of Sciences)

**Lead Authors:** Javier Naupari (Universidad Nacional Agraria La Molina)

**GEO Fellows:** Darshini Ravindranath (University College London), Hung Vo (Harvard University), Ying (Grace) Wang (Tongji University)

# Executive summary

**Land resources are essential for achieving 10 of the 17 Sustainable Development Goals (SDGs).** Agricultural and food production are still responsible for most of the changes of land, including forests and other types of ecosystems, while human-induced land degradation remains a fundamental environmental problem affecting food security, livelihoods and lives of the people on this planet. Globalization, population growth, urbanization and shifting dietary preferences are responsible for some of the changes in our food system over the past 50 years and have increased food imports and teleconnections. There is also a growing concern over land grabbing and speculation throughout the world. Clear property rights and land-resource stewardship are crucial for ensuring sustainable production of food while preserving the ability of land ecosystems to continue providing a wide variety of other benefits to people (e.g. hydrological regulation, pollination). Rural inhabitants play a fundamental role in land conservation. The main findings regarding land can be summarized as follows.

**Current trends, based on technological optimism, improved seeds, machinery and fertilizers, are not likely to supply future demands for food, energy, timber and other ecosystem services and values taking into consideration even moderate projections for land-resource availability** (*well established*). By 2050, the world needs to produce at least 50 per cent more food to feed the projected global population of 10 billion people. Current land management cannot achieve this while preserving ecosystem services, the loss of natural capital, combating climate change, addressing energy and water security, and promoting gender and social equality. {8.5.1}

**Food production is the largest anthropogenic use of land, accounting for 50 per cent of habitable land** (*well established*). Livestock production uses 77 per cent of agricultural land for feed production, pasture and grazing land. The livestock sector provides only 17 per cent of dietary energy and 33 per cent of dietary protein demands. Therefore, using about 80 per cent of agricultural land for livestock is inefficient. {8.4.1}

**The expansion of agricultural area has been slowed by increasing productivity** (*established but incomplete*). Although there are regional variations, globally, the harvested crop area increased by 23 per cent between 1984 and 2015, while global crop production rose by 87 per cent. On average, per capita daily food supply in the world increased 10 per cent between 1993 and 2013. However, monocultural farming systems, sometimes assumed to be more productive and profitable, are often associated with environmental degradation and biodiversity loss. Grasslands in southern South America have been converted into soybean fields mostly for export. The expansion of oil palm in South-East Asia has been at the expense of forests and peatlands. {8.4.1}

**Global food supply has become dependent on the growing trade of a small number of crops grown in a few regions with increasing crop specialization** (*well established*). The share of production traded internationally in 2014 was 24, 11 and 60 per cent of global wheat, maize and soybean production, respectively. This leads to lower food prices and food-deficit

countries benefit from these food imports. However, the geographic concentration of production increases systemic risk, as illustrated by recent spikes in international commodity prices due to poor harvests in certain regions. Furthermore, the growing prevalence of certain crops in global food supplies has contributed to the increasing consumption of nutritionally poor, highly processed foods, with potentially serious consequences for population health. {8.5.1}

**The linkages between different places (teleconnections) are strengthening worldwide** (*well established*). Demand in some places generates land transformations in others. The distance between producers and consumers may obscure ecosystem degradation in production areas. For example, demand for land resources in many urban areas is affecting land use in rural and other urban areas, both within national boundaries and internationally. {8.3.2}

**Approximately one-third of food produced globally for human consumption is lost or wasted** (*well established*). Approximately 56 per cent of total food loss and food waste occurs in industrialized countries, while 44 per cent originates from developing countries. {8.5.1}

**Deforestation rates differ among regions, and while the global trend is continuing forest loss, many regions, especially in more developed countries, are showing an increase in forest cover (mostly in plantations)** (*well established*). In the 1990s, about 10.6 million ha of natural forests were lost per year. For the period 2010-2015, this rate had dropped to 6.5 million ha/year. Simultaneously, the growth rate of planted forests is about 3.2 million ha/year, and by 2015 they accounted for 7 per cent of the global forest area mostly concentrated in high-income countries. Plantations do not provide the same diversity of ecosystem services as natural forests. {8.4.1}

**Although built-up areas represent only a relatively small fraction of land, their impacts extend beyond built areas** (*well established*). Since 1975 urban settlements have grown approximately 2.5 times, accounting for 7.6 per cent of the global land area in 2015. Cities and infrastructure expand differently across regions. By covering the ground with impervious surfaces, cities affect the hydrological cycle and soil function, as well as generating urban heat islands. About 3 billion urban dwellers lack access to adequate waste disposal facilities, which poses health risks (infections, exposure to chemicals, dust, others) and generates environmental impacts (soil and water pollution, greenhouse gas [GHG] emissions, others) and land-use competition. {8.4.1; 8.5.2}

**Land is the most important asset for people in large sections of the world and secure rights can help turn these assets into development opportunities** (*well established*). Indigenous populations, the poor, landless and women are among the groups most vulnerable to the implications of unequal landownership and access. Estimates suggest that only about 10 per cent of formal land rights are registered or recorded worldwide. Without formal recognition and protection of their land rights, communities in some countries face loss of land

due to land acquisition, land grabbing and land leasing amid fear of food scarcity and rising food prices. Around the world, 26.7 million ha of agricultural land have been transferred into the hands of foreign investors since 2000. {8.5.3, 8.5.4}

**Unequal tenure of land resources is a critical challenge for sustainable land management** (*well established*). Tenure-security of indigenous peoples' lands can generate billions of dollars' worth of benefits (carbon sequestration, reduced pollution, clean water, erosion control) and a suite of other local, regional and global 'ecosystem services'. These benefits far outweigh the costs of securing land tenure. {8.5.3}

**Continuing on the current track, it will be difficult to achieve the land degradation neutrality target adopted in the United Nations Conference on Sustainable Development (Rio+20)** (*well established*). Assessments based on satellite data show that land degradation hotspots cover about 29 per cent of global land area. However, there is variance between different data sets and disagreement between methods. About 3.2 billion people live in these degrading areas. Investing in avoiding land degradation and the restoration of degraded land makes sound economic sense; the benefits generally far exceed the cost. Innovative technologies, land management strategies and land-resource stewardship at different scales (e.g. good agricultural practices, sustainable forest management, agro-

silvopastoral production systems, agricultural innovation, payment for ecosystem services, land restoration, land titling) need to be more effectively promoted and adopted at local, regional, international and national levels. These alternatives also contribute to climate change resilience. Existing multilateral environmental agreements provide a platform of unprecedented scope and ambition for action to avoid and reduce land degradation and promote restoration. {8.6.1; 8.6.3}

**Decreasing the gender gap in access to information and technology, and access to and control over production inputs and land, could increase agricultural productivity and reduce hunger and poverty** (*well established*). New policies should explicitly target indigenous peoples, women, family farmers, pastoralists and fishers, so these groups can have secure and equitable access to land, inputs, knowledge, resources, markets, financial services, opportunities for adding value and non-farm employment. {8.6}

**Minimizing food losses and waste will have significant environmental, social and economic benefits in supporting global food security** (*well established*). Where waste cannot be prevented, opportunities to recover value from this waste stream, such as conversion to compost, liquid fertilizers, biogas or higher value end-use products such as animal feed protein or biochemicals, should be pursued. {8.6}

## 8.1 Land resources and the Sustainable Development Goals

Land is complex to define as it has multiple interconnected dimensions (e.g. land as a provider of resources and services, as shelter, as property, as a key to cultural identity) (United Nations Convention to Combat Desertification [UNCCD] 2017). In this chapter, we emphasize land as a provider of food, fodder, fibre and forest products. Its ability to provide ecosystem services that regulate ecological processes is treated in Chapter 6 and the latest Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES) assessment reports (see below). Land is where a large proportion of food is produced, therefore it is closely related to Sustainable Development Goal (SDG) 2: End hunger, achieve food security and improved nutrition and promote sustainable agriculture. Specific targets for this goal include ensuring access to sufficient, healthy and nutritious food, especially for the most vulnerable groups. Furthermore, SDG 2 is closely related to increasing productivity through sustainable food production systems that are more resilient under increasing threats of climate change, and for maintaining and improving soil quality for future generations. Sustainable and more resilient food production systems require working towards gender equality and reducing other forms of inequality (SDG 10) since men and women do not have equal access to land resources in many parts of the world.

Land is the home of terrestrial biodiversity, is associated with food production, is where people live and where most economic activities take place. Over 54 per cent of the global population lives in urban areas (United Nations 2015a) and this poses additional challenges for land management: how to deal with hazardous pollutants and chemicals and their impacts on people and the environment. Pollution on land is becoming an important pressure, and human-generated waste and chemicals are impacting the health of people and the functioning of many ecosystem processes (SDGs 3, 15).

Additionally, human use of land is exerting enormous pressure on land resources, privileging short-term gains over long-term sustainability (UNCCD 2017), decreasing the supply of many ecosystem services (nature's contributions to people). The Millennium Ecosystem Assessment presented evidence that we are living beyond our means (Millennium Ecosystem Assessment 2004) and that ecosystems' abilities to provide us with food, fibre, forest resources, fodder and other biodiversity-related benefits are threatened. The recent IPBES report on land degradation and restoration reinforces this critical message (Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services [IPBES] 2018). A healthy planet is the basis for development, and sustainable land-resource management is at the core of this challenge.

## 8.2 Setting the stage for GEO-6: the GEO-5 legacy

The main messages of the fifth report of the *Global Environment Outlook* (GEO-5) could be extrapolated to GEO-6. Perhaps the most important difference is the recognition of climate change as a driver of environmental change, and how it has the potential for altering land resources on its own (see Chapter 2). Climate change usually exacerbates ecosystem degradation and a more variable climate degrades ecosystems more strongly.

Another difference is the increasing recognition of the critical function that clear property rights play for land-resource stewardship and the crucial role of rural inhabitants in land conservation. The Land Rights Now initiative (<http://www.landrightsnow.org>) states that 2.5 billion people depend on land resources that are held, managed or used collectively. These people manage and protect 50 per cent of land, but only have legal ownership of 10 per cent. Clear property rights usually result in better management and stewardship of land resources (Lawry *et al.* 2017). Without them, these people are vulnerable to land dispossession in the hands of powerful actors (e.g. multinationals, governments).

Finally, there is increased concern over how land resource degradation is leading to widespread migration and even conflict. Since recording of these instances began in 2015, the Environmental Justice Atlas (<https://ejatlas.org/>) has listed more than 2,000 cases of socioenvironmental conflicts across the globe where land mismanagement, largely due to poor governance, has led to land degradation, conflict and/or dispossession of resources.

## 8.3 Drivers and pressures

### 8.3.1 Population

As chapter 2 notes, population growth is a key driver of land-use transformation with its associated environmental impacts. In the developing world, particularly Africa, there will be a doubling or tripling of population by the mid-21st century (United Nations 2014). In contrast, by 2050 developed countries will experience only small increases or even decreases in their population (United Nations 2015). Since the developed world has already entered a post-industrial society based increasingly on the tertiary sector, it is expected to be more stable in terms of land use, while developing countries are currently experiencing a rapid transition from agrarian societies to the industrial regime, with consequent radical change in land- and resource-use patterns (Haberl *et al.* 2011).

Population growth can present a serious threat to the inherent limits of land to provide food, shelter and appropriate nutrition for local communities. However, impacts depend on specific socioeconomic contexts and are present mostly in developing countries. For example, a study of land-use change in north-western Ethiopia (1972-2010) shows conversion of 62 per cent of woodland into cropland, with high environmental costs (dust storms, droughts, severe soil erosion), due to population growth, but also because of attractive subsidies to farmers (Zewdie and Csaplovics 2015). Most studies on the subject recognize the importance of rural-to-urban migration for mitigating some of the negative impacts of population growth on land resources in rural areas. Some natural increase in population in rural areas can now be absorbed outside the country due to intraregional infrastructure improvements, as observed in Africa where a majority of migrants circulate within the continent looking for economic opportunities (Awumbila 2017).

### 8.3.2 Urbanization

Urban and rural areas are interconnected in terms of people, resources and services. Rural areas are connected to urban regions through networks of roads, information technology, electricity and trade. Meanwhile, urban areas are increasingly reliant on land-based resources yielding nature's contributions to people such as clean water, food and fibre. Urbanization can

both positively and negatively impact these flows and functions and influence the economy and development of peri-urban and rural areas (Brenner and Schmid 2014). Cities operate within ecosystems that usually extend beyond jurisdictional boundaries (Solecki and Marcotullio 2013), requiring new methods to accurately measure the extent of urbanization to aid decision makers and civil society in responding to existing and emerging challenges (United Nations 2016). Urban demands for food, water, fibre and construction materials have established strong linkages between cities, rural areas and even regions in other countries. These linkages, also known as teleconnections, mean that land use in rural areas increasingly depends on demands from distant, urban agglomerations (Seto *et al.* 2012; Bergmann and Holmberg 2016). Urban infrastructure (energy, water, buildings and transportation) and food supply are particularly reliant on transboundary supplies (Kennedy and Hoornweg 2012; Ramaswami *et al.* 2012; Ramaswami *et al.* 2017).

Rural-to-urban migration continues and it has multifaceted impacts on land use through changing diets and demands on infrastructure and housing, as well as the ability of land to continue providing nature's contributions to people (UNCCD 2017). Much of the increase in population in built-up areas has taken place in disaster-prone regions such as within 10 metres (above sea level) of low elevation coastal zones (Seto *et al.* 2011; Paresi *et al.* 2016).

Figure 8.1: Different perspectives on the globalization of lands in 2007 (Eckert IV projection)

The figure illustrates how capital and consumption are linked regionally and globally for different lands' economic activities.

Source: Bergmann and Holmberg (2016).

### 8.3.3 Economic development

Globalization forces exert increasing pressures on land systems and their functions, leading to landscape change (Fischer-Kowalski and Haberl 2007; Henders and Ostwald 2014; Schaffartzik *et al.* 2015). Global trade and capital flows influence land use (e.g. agriculture, forestry) in developing countries (Bergmann and Holmberg 2016) (**Figure 8.1**, **Figure 8.2**). These flows of agricultural goods require transport and storage, which may increase economic and environmental costs and may also lead to the deterioration of the nutritional value of food, increase risks of disease transmission and generate food waste (UNEP 2016a). The significance of pressures on land tenure and land access is discussed in further detail in Section 8.5.3.

### 8.3.4 Technology and innovation

Around the globe, fast advancing technologies shape production and consumption, and drive patterns of land use and terrestrial ecosystems at various scales. Earth's big data and citizen science improve environmental monitoring and assessment, while allowing more public involvement (see Chapter 25).

Although it still has some limitations, satellite-based Earth observation has been combined with big data to track forest changes worldwide (e.g. Global Forest Watch, [www.globalforestwatch.org](http://www.globalforestwatch.org); Terra-i, [www.terra-i.org](http://www.terra-i.org)). Drones, powered by mobile technology, are becoming widely used to monitor biomass burning and unauthorized land-use conversion. The global explosion of cell phone access, and especially smartphones, can be used to democratize data access. Technological developments such as precision

agriculture and drip irrigation are examples of more efficient agrochemical and water use.

Mobile communication and the Internet enable critical environmental information to spread within seconds to any corner of the world, rich or poor. Rural inhabitants in many parts of the developing world can use these technologies to improve land management with potential impacts on biodiversity conservation and land use (Chin 2018).

**Figure 8.2: Relative roles played by agricultural commodities versus manufactures and services in globalizing lands (Eckert IV projections)**

Source: Bergmann and Holmberg (2016).

### 8.3.5 Climate change

Rising global temperature and changing rainfall patterns have already impacted terrestrial ecosystems and crop yields (see **Figure 8.3**). In tropical regions, the effects of higher temperatures will likely be greater than in temperate zones (Intergovernmental Panel on Climate Change [IPCC] 2014). Shifting rainfall patterns may benefit certain regions, but greater variability in precipitation (more frequent droughts) poses a risk to 70 per cent of global agriculture that is rain-fed (IPCC 2014). As the growing seasons change, yield growth has slowed (Lobell, Schlenker and Costa-Roberts 2011; Lobell and Gourdji 2012). Rising sea level due to climate change generates risks of coastal area loss and subsidence (IPCC 2014), threatening the livelihoods of many coastal inhabitants (Paresi *et al.* 2016) (see Section 8.3.5).

Increased concentrations of CO<sub>2</sub> in the atmosphere may benefit crop yields in certain regions through greater CO<sub>2</sub> fertilization (McGrath and Lobell 2013), while warmer temperatures could bring yield gains in high-latitude regions (IPCC 2014). At a global level, however, yields are expected to suffer as average temperatures and ozone concentrations in the troposphere continue to rise (Schlenker and Roberts 2009; IPCC 2014). Higher temperatures have led to increased distribution of certain weeds and pests (Pautasso *et al.* 2012) and have exacerbated existing stresses during certain growing periods (Gourdji, Sibley and Lobell 2013).

On the other hand, climate-smart agricultural practices such as minimum tillage and energy-efficient crops and practices present an opportunity for increasing the atmospheric carbon sink in soils and hence contribute to mitigation of climate change (Han *et al.* 2018). Similarly, efforts to reduce deforestation and forest degradation, conserve and enhance

forest carbon stocks, and sustainably managed forests globally can contribute significantly to reducing greenhouse gas (GHG) emissions and to carbon sequestration in living biomass and forest products.

**Figure 8.3: Estimated net impact of climate trends for 1980-2008 on crop yields by country**

Source: Lobell, Schlenker and Costa-Roberts (2011).

## 8.4 Key state and trends

### 8.4.1 Land-use dynamics

#### Land-cover change

Land is extremely dynamic and land cover changes due to climatic, geologic or ecological processes. However, human land use, mostly agriculture, is currently responsible for most of the changes of land cover and its condition (Haberl 2015; de Ruiter *et al.* 2017; **Figure 8.4**).

Agricultural production needs to nearly double in the period 2012-2050 to meet increasing food, feed and biofuel demand (Food and Agriculture Organization of the United Nations [FAO] 2017a). Although the Food and Agriculture Organization of the United Nations (FAO) estimates that 1,400 million ha are available for expansion (Alexandratos *et al.* 2012), these are

mostly in forests and other ecosystems with little disturbance, where nature's contributions to people such as clean water and climate regulation are generated (Machovina, Feeley and Ripple 2015). When possible, people abandon degraded land and expand production elsewhere. As land becomes abandoned, it may slowly start to regenerate: vegetation and wildlife begin to reclaim the spaces left by the abandoned land use, as the spontaneous regrowth of 362,430 km<sup>2</sup> of woody vegetation in Latin America (2000-2010) illustrates (Aide *et al.* 2013).

Global economic forces are shaping local land-use patterns. For example, modern mining is growing in scale due to increased global demand. This is compounded by declining ore grades, which means more ore needs to be processed to meet demand, with extensive use of open cast mining and its associated waste rock. Mining presents cumulative environmental impacts, especially in intensively mined regions,

**Figure 8.4. Changes of global forests (top) and cropland (bottom) 1992-2015 based on European Space Agency land cover data time series**

Source: Adapted from European Space Agency (2015).

including areas subject to hydraulic fracturing for oil. A map of areas in Colombia, Ecuador, Peru and Bolivia (Figure 8.5) shows land areas that are or have the potential to be exploited for mining, gas and oil highlights the conflict that can emerge from land-use competition (Asociación Pro Derechos Humanos [Aprodeh] *et al.* 2018).

### Agricultural dynamics

Food production accounts for the largest anthropogenic use of land – 38 per cent of ice-free land (Holmes *et al.* 2013) or 50 per cent of habitable land (Roser and Ritchie 2018). Within this, the livestock sector dominates, using more than three-quarters of agricultural land for feed production, pasture and grazing (Foley *et al.* 2011; Roser and Ritchie 2018) (Figure 8.6).

Primary food production accounts for about 23 per cent of agricultural land use (Figure 8.6), although in recent years a growing proportion of land has been used to grow crops for biofuel production (Cassidy *et al.* 2013). By 2009, biofuel production accounted for 2 per cent of total ice-free land use and is expected to increase to 4 per cent by 2030 (FAO 2009). Agricultural area has decreased by about 1 per cent since 2000 (Figure 8.7; FAO 2017b). Although a small drop, this figure does not consider land degradation (see below) or how, despite the reduction in the total agricultural area, this may mask the abandonment of degraded lands and the expansion of the agricultural frontier elsewhere.

While the global harvested crop area increased by 23 per cent between 1984 and 2015, global crop production rose by 87 per cent (FAO 2017b), mostly through monoculture farming. However, these food production systems might be associated with environmental degradation and biodiversity loss (Benton, Vickery and Wilson 2003; Foley *et al.* 2011; UNCCD 2017).

**Figure 8.5: Areas designated for extractive activities in the Andean region (South America)**

**Figure 8.7: Agricultural area 2000-2014**

Agricultural area includes the area under agriculture (arable land), permanent crops, and pasture and meadows in a given year.

Source: FAO (2017b).

Similarly, per capita daily food supply in the world increased 10 per cent between 1993 and 2013 (**Figure 8.8**, FAO 2017b). Many areas have been converted to cropland as the demand for flexible crops increases (Borras *et al.* 2012). Grasslands in Argentina, Bolivia, Brazil, Paraguay and Uruguay have been converted into soybean fields mostly for export (Graesser *et al.* 2015). Soybean area has more than doubled since 2000 (**Figure 8.9**). The areas harvested in South America and North America account for approximately 47 per cent and 30 per cent, respectively, of the soybean area worldwide (FAO 2017b).

A similar process occurs with oil palm production in South-East Asia. The area planted with this crop has increased since 2000

**Figure 8.9: Soybean production in South America 2000–2014**

Source: FAO (2017b).

(**Figure 8.10**). In 2014, more than 68 per cent of total oil palm crop area was in this region and 85 per cent was in Asia (FAO 2017b).

The expansion of oil palm plantations in South-East Asia has been at the expense of forests. This increase has been the result of the rising demand for biofuels and edible oil. In Kalimantan, Indonesia, from 1990 to 2010, some 90 per cent of land converted to oil palm plantations were forested (Carlson *et al.* 2012). From 2001 to 2015, more than 9.5 million ha were deforested on Borneo (World Resources Institute [WRI] 2018). In the oil-palm plantations in the lowlands of peninsular Malaysia (2 million ha), Borneo (2.4 million ha) and Sumatra (3.9 million ha), Koh *et al.* (2011) found that about 880,000 ha of tropical peatlands in the region had been converted to oil palm plantations by the early 2000s. By 2010, some 2.3 million ha of peat-swamp forests were deforested but were not yet converted to oil palm plantations.

**Figure 8.8: Food supply in the world (kcal/capita per day)**

Source: FAO (2017b).

**Figure 8.10: Production of oil palm fruit in South-East Asia**

Source: FAO (2017b).

Global livestock populations increased between 2000 and 2014 (Figure 8.11, Figure 8.12). While human population grew by nearly 19 per cent, numbers of cattle and buffalo, goat and sheep, poultry birds and pigs grew by 13.8 per cent, 21.9 per cent, 45.4 per cent and 15.1 per cent respectively. However, the increase in livestock numbers has been accompanied by a decrease in pasture and permanent meadows (Figure 8.13). These high growth rates are mostly associated with more intensive livestock production systems that rely on the efficient use of animal feed (Mottet *et al.* 2017).

**Figure 8.11: Numbers of herbivores and poultry**

Source: FAO (2017b).

**Figure 8.13: Permanent meadows and pastures (1,000 ha)**

Source: FAO (2017b).

#### Forest dynamics

Forests continue to decline (Figure 8.14). In 1990, they represented 31.6 per cent of the planet's land area. This decreased to 30.6 per cent in 2015 (FAO 2015a), but forest loss rates are declining. In the 1990s, about 10.6 million ha of natural forests were lost each year. For the period 2010-2015, this rate had dropped to 6.5 million ha/year. At the same time, the increase in planted forests was about 3.2 million ha/year; by 2015 they accounted for 7 per cent of the global forest area mostly concentrated in high-income countries (FAO 2015a; Figure 8.15). Forest loss rates differ among regions and, while the global trend is towards forest loss, many regions, especially

**Figure 8.14: Forest land in the world, 2000-2015**

Source: FAO (2017b).

Figure 8.15: Forest area annual net change, (1990-2000, 2000-2010, 2010-2015)

Source: FAO (2015a).

in more developed countries, are showing an increase in forest cover, though some of this forest is as plantations. Natural forests continue to decline in most areas of the world (**Figure 8.15**), threatening the supply of essential benefits to people. For example, as deforestation increases in the Amazon rainforest, rainfall has been decreasing. Recent estimates indicate that a critical tipping point for the hydrological cycle in this part of South America will be reached if deforestation reaches 20-25 per cent of the original forest cover in the Amazon basin (Lovejoy and Nobre 2018). In the last 50 years, 17 per cent of the original extent of the Amazon rainforest has been deforested (World Wide Fund for Nature [WWF] 2018) and the forest cover continues to decrease (Butler 2017; WRI 2018; WWF 2018).

### Urban expansion

Built-up areas occupy a very small fraction of land. However, since 1975 urban clusters (i.e. urban centers as well as surrounding suburbs) have expanded approximately 2.5 times, accounting for 7.6 per cent of global land area (Paresi *et al.* 2016). Between 1975 and 2015, built-up areas doubled in size in Europe, while in Africa they grew approximately fourfold. Cities have grown in both regions, but urban population remained relatively constant in Europe while it tripled in Africa. This means that the built-up area per-capita is different across the world (Paresi *et al.* 2016). In addition, urban expansion leads to landscape fragmentation and urban sprawl. As cities expand, urban land uses usually take over agricultural lands (van Vliet, Eitelberg and Verburg 2017), and the demand for food, fibre and minerals can transform previously unconnected locations (Seto *et al.* 2012; van Vliet, Eitelberg and Verburg 2017). In Latin America, a pervasive spatial expansion (almost 84 per cent of the population lives in cities) has been observed leading to less compactness (Inostroza, Baur and Csaplovics 2013).

By covering the ground with impervious surfaces, cities affect the hydrological cycle and soil function. They also generate what are called urban heat islands. But they can also be more efficient in providing access to education, housing, clean water and electricity. Since 2000, cities have incorporated more green spaces and trees (Paresi *et al.* 2016).

While cities are expanding into hinterlands, there is increasing recognition of the value of preserving natural systems (e.g. lakes and natural water bodies) as well as constructing enhanced-engineered urban green infrastructures (e.g. parks, urban farms, bioswales). These have potential to offer multiple benefits that can enhance biodiversity and human well-being, including water management, flood risk mitigation; heat island mitigation (Pataki *et al.* 2011); emotional well-being, health (Groenewegen *et al.* 2006; Pataki *et al.* 2011; White *et al.* 2013; Sturm and Cohen 2014; World Health Organization [WHO] 2017); pollution capture; and cultural amenities.

In 2015, some 52 per cent of people lived in high-density urban centres, 33 per cent in towns and suburbs and 15 per cent in rural areas (Paresi *et al.* 2016). While many cities continue to grow in population and expand, others experience population decline. Shrinking cities leave behind vacant parcels as part of a cycle of growth and decline, whose management offers new opportunities to enhance the environment.

### 8.4.2 Land quality dynamics

#### Land degradation and crop production

Land degradation involves the decline or disruption of land ecosystem services, including net primary production (NPP) (Le, Nkonya and Mirzabaev 2016). It results from different processes: soil erosion, salinization, compaction and contamination, organic matter decline, forest fires and

**Figure 8.16: Natural forest area by region, 1990-2015**

Source: FAO (2015a).

overgrazing (Jones *et al.* 2012; Kosmas *et al.* 2014). Decline of NPP is also a reduction in microbiological activity and water retention capacity, lower hydraulic conductivity, and decreasing soil resistance, among others (Soane *et al.* 2012). FAO (2015b) estimates current land degradation at 12 million ha/year. It is estimated that annual losses from ecosystem services resulting from land degradation range between US\$6.3 trillion and 10.6 trillion (The Economics of Land Degradation [ELD] 2015). While degradation could be a biophysical phenomenon, the causes and implications are also economic and social. Many efforts attempt to assess observable land degradation trends, scales and consequences. However, different definitions of degradation and methods used to measure them lead to differing results regarding its magnitude, where it takes place, its effects and its costs (FAO 2018). A recent estimate using satellite imagery estimates that 29 per cent of global land area is degraded, while improvement has occurred in 2.7 per cent of global land area in the last three decades, and about 3.2 billion people live in the degrading areas (Le, Nkonya and Mirzabaev 2016). Reducing land degradation and increasing land restoration are critical for providing necessary ecosystem services that contribute to life on Earth and human well-being (IPBES 2018).

### Desertification

The United Nations Convention to Combat Desertification (UNCCD) defines desertification as “land degradation in arid, semi-arid, and dry sub-humid areas resulting from various factors, including climatic variations and human activities” (UNCCD 1994). However, desertification is still a highly controversial issue usually leading to expert disagreement (Reynolds and Smith 2002; Bestelmeyer *et al.* 2015). The extent of desertification ranges from 15 per cent to 63 per cent globally as well as 4 per cent to 74 per cent for drylands (Safriel 2007), and can be equally variable within a country like Mongolia, where degradation estimates range from 9 per cent to 90 per cent (Addison *et al.* 2012).

Recent research (Global Assessment of Soil Degradation [GLASOD]) shows that previous generalizations claiming that land degradation is occurring in semiarid areas worldwide is not supported by satellite-based observations (de Jong *et al.* 2011; Fensholt *et al.* 2012; Cherlet *et al.* 2018). Desertification and drought research in the Sahel indicate that the first process is not taking place (Behnke and Mortimore 2016). This trend may be explained by increasing precipitation, as well as by lower pressure on land due to outmigration (Olsson, Eklundh and Ardö 2005). However, current climatic conditions in the Sahel appear to be still below the more humid conditions of 1930-1965 (Anyamba and Tucker 2005; Nicholson 2013).

A positive trend is also observed in semi-arid areas of China where human actions might explain the ‘expansion of desertification’ between 1980 to 1990, although conservation activities have begun to reverse these trends (1990-2000) (Xu *et al.* 2009). Recent modelling results indicate that global greening might also be caused by CO<sub>2</sub> fertilization, nitrogen deposition and climate change (Zhu *et al.* 2016).

Recognizing the inherent complexity underlying land degradation, the recent edition of the World Atlas of Desertification (WAD) (Cherlet *et al.* 2018) presents several global data sets of biophysical and socioeconomic

processes that, individually or combined, can contribute to land degradation (Reynolds *et al.* 2011; Bisaro *et al.* 2014).

### Soil salinization

In arid and semi-arid regions, lack of adequate drainage in irrigated areas triggers salt accumulation in the root zone, negatively affecting crop productivity and soil properties (Qadir *et al.* 2014). In some countries, soil salinization affects half of irrigated land (Metternicht and Zinck 2003). Other sources suggest that about 33 per cent of the globally irrigated area has declining productivity due to inadequate irrigation, causing waterlogging and salinization (Khan and Hanjra 2008). Several studies of grain yield losses due to salinization indicate grain yield losses of 32-48 per cent on average (Murtaza 2013). The global annual losses in irrigated crops caused by salt-induced land degradation could be about US\$27.3 billion due to lost crop production (Qadir *et al.* 2014). The costs of inaction on these lands may result in 15-69 per cent revenue losses depending on the type and intensity of land degradation, crop variety and irrigation water quality and management (Qadir *et al.* 2014). Additional losses, which are not included in these estimates, cover a wide range of issues – from deterioration of animal health to decline in property values of affected farms, among others (Qadir *et al.* 2014).

### Permafrost thawing

Due to various feedbacks in the climate system, warming in the Arctic currently exceeds twice the mean global temperature rise (Taylor *et al.* 2013a). Sea ice is retreating, permafrost is thawing, and the ice-free season is lengthening, such that waves and warm air are increasingly degrading the thawing permafrost in the interior, as well coastal areas. The thawing of permafrost releases GHGs and alters the landscape. Thaw reduces soil and landform stability, increases erosion and affects arctic habitat, albedo and hydrology.

© Shutterstock/Danila Delmont

By far, the largest fraction of the Arctic coastline consists of thawing permafrost (**Box 8.1**). Arctic permafrost coasts represent 34 per cent of all coasts on Earth. Coastal erosion rates have increased in recent years with values ranging around 1 metres /year. Erosion rates are highest along the Alaskan and Siberian coastlines, with maxima as high as

25 metre/year (**Figure 8.17, Figure 8.18**) (Günther *et al.* 2013; Overduin *et al.* 2014; Fritz, Vonk and Lantuit 2017). Therefore, increasing fluxes of organic carbon are released into the shelf seas. In some locations (Alaska), villages have had to be relocated further inland.

### Box 8.1: Livelihood impacts in the Arctic

Reindeer (caribou) herds are an important part of Arctic ecosystems and integral to the livelihoods of indigenous peoples in Alaska, Arctic Canada, Scandinavia and the Russian Federation. Reindeer-herding communities depend on access to seasonal pastures. The seasonality and extent of pastures is changing as a result of climate change, impacting these pastoral communities.

Mining and resource extraction are also important in the Arctic. Changing Arctic conditions have made the construction and operation of the winter ice roads that supply mining outposts problematic. A warming climate has delayed freeze-up in the autumn (fall) and produced an earlier spring melt as well as thinner ice during the winter. This has led to shorter winter-road seasons. As the Arctic climate continues to warm, co-management institutions will find themselves increasingly dealing with trade-offs between sustainable development and sociocultural and ecological integrity of Arctic lands and livelihoods.

## 8.5 Key impacts

### 8.5.1 Food security

People are considered food secure when they always have availability of and adequate access to sufficient, safe, nutritious food to maintain a healthy and active life (FAO *et al.* 2017). The discussions in this section cover three critical issues—food availability, food access and food utilization.

#### **Hunger and malnourishment**

A sizeable proportion of the world's seven billion people are hungry and malnourished. Roughly one billion people have energy-deficient diets, and about one billion people suffer from diseases of energy surplus (called the 'hidden hunger' of micronutrient deficiencies) (Godfray and Garnett 2014). Although undernutrition is slowly declining, 155 million children under five years old, mostly in sub-Saharan Africa

and South Asia, still suffer from stunted growth.

Simultaneously, increasing numbers of people are suffering from overnutrition: more than 2 billion adults are overweight and 500 million are obese. Moreover, 88 per cent of countries face two or three forms of malnutrition (Development Initiatives 2017), and undernutrition and obesity increasingly coexist in the same households (FAO *et al.* 2017).

Malnutrition and changing consumption patterns put greater pressure on land resources making land-use decisions more important than ever before. Most food is sourced from terrestrial environments, though 17 per cent of global animal protein and 6.7 per cent of all protein consumption is from fish (FAO 2016). While food costs have fallen since 2008, this trend has not been constant (FAO 2017c), with volatility attributed to increased demand from rapidly developing countries and competition among first-generation biofuel producers.

(The Royal Society 2008; Godfray *et al.* 2010). **Figure 8.19** shows vulnerability to food security using meteorological data for the period 1981–2010 and socioeconomic data representative of the year 2010. The results indicate that disasters such as floods and droughts are already having a strong impact on food security, and their frequency and intensity may increase as a result of climate change (Met Office Hadley Centre and World Food Programme 2018). In developing countries, agriculture absorbs about 22 per cent of the total damage and losses caused by natural hazards (FAO 2015b). Although disasters may impact rural livelihoods directly, the disruption to agricultural production and development can have negative repercussions across national economies, with devastating effects on food security, including in urban areas (**Box 8.2**).

### **Sustainable food production and efficient use**

Approximately one-third of the food produced globally for human consumption is lost or wasted (Lipinski *et al.* 2013; United Nations Environment Programme [UNEP] 2015), together with the resources used in its production (land, energy, water, etc.) with the associated environmental impacts. Food losses and waste in 2007 utilized almost 1.4 billion ha of land, equivalent to about 28 per cent of the world's agricultural land area (FAO 2013). Based on food crop data for the period 2005–2007, food losses and waste consumed 23 per cent of total global fertilizer use (28 million tons/year) and 24 per cent of total freshwater resource use (Kummu *et al.* 2012). Furthermore, an estimated 99 per cent of food wastage at the agricultural production stage is produced in areas where soils are facing medium to strong land degradation, placing further stresses on these areas (FAO 2013, p. 47).

Approximately 56 per cent of total food loss and food waste occurs in developed countries, while 44 per cent originates from developing countries (Lipinski *et al.* 2013). This wastage generates GHGs. If food wastage were a country, it would be the third largest emitting country in the world (FAO 2015c). In the global South, losses are mainly due to the absence of food-chain infrastructure and lack of knowledge or investment in storage techniques. In the global North, pre-retail losses are lower but those arising from retail, food service and home

### **Box 8.2: The Syrian crisis: droughts and land degradation as factors**

The Syrian conflict has sometimes been labelled a 'climate conflict', since some of the root causes could be traced to the drought that affected the country between 2007 and 2010 (Kelley *et al.* 2015), the worst drought on record, causing widespread crop failure in the region. In Syrian Arab Republic, some 1.5 million people from rural farming areas migrated to the peripheries of urban centres, leading to a spike in food prices and eventually to the upheaval of the population (Kelley *et al.* 2015). The government could not provide migrants with housing, jobs and economic opportunities. This combination of factors contributed to a war that has now lasted several years and left the country in ruins, with about two-thirds of its 22 million population displaced.

stages of the food chain have grown dramatically in recent years (Godfray *et al.* 2010; **Figure 8.20**).

Sustainable intensification (e.g. agroecology-based production, agricultural innovation) is promoted as a sustainable land management strategy. Besides a sustainable food supply, it maintains nature's contributions to people, promotes human health and nutrition (Pretty, Toulmin and Williams 2011; Robinson *et al.* 2015).

### **Food security and food trade**

International trade is increasingly important to meeting global food demand (Nelson *et al.* 2010; MacDonald *et al.* 2015). Population growth, urbanization and shifting dietary preferences have increased dependency on food imports (Msangi and Rosegrant 2011; Alexandratos *et al.* 2012; Porkka *et al.* 2013). The proportion of the global population living in food-deficit countries rose from 72 per cent in 1965 to 80 per cent in 2005 (Porkka *et al.* 2013).

Just under one-quarter of all food produced for human consumption is traded on international markets (D'Odonico *et al.* 2014; **Figure 8.21**).

**Figure 8.19: Potential impacts of climate change on food security**

Source: Met Office Hadley Centre and World Food Programme (2018).

**Figure 8.20: Make-up of total food waste in developed and developing countries**

Retail, food service and home and municipal (subnational government sphere) categories are presented together for developing countries.

Source: Godfray *et al.* (2010).

Some low-income food-deficit countries have capacity to increase food productivity. But in others, including those where food insecurity is high – for example, Eritrea, Burundi and Somalia – food availability from domestic production is falling and the capacity to increase production is limited (Fader *et al.*

**Figure 8.21: Share of global production volumes traded internationally in 2014**

Source: Chatham House (2017); FAO (2017b).

2016). Most developing countries have become increasingly reliant on imports to meet domestic demand, a trend that will likely continue through to 2050 (Alexandratos *et al.* 2012; **Figure 8.22**).

Global food supply has become dependent on the growing trade of a small number of crops grown in a few 'breadbasket' regions with increasing specialization (Khoury *et al.* 2014). This has led to lower food prices, with food-deficit countries benefiting from these food imports. However, the geographic

**Figure 8.22: Developing countries: net cereals trade (million tons)**

Net cereal imports have increased since 1970 and are expected to rise.

Source: Alexandratos *et al.* (2012).

concentration of production increases systemic risk, as illustrated by recent spikes in international commodity prices due to poor harvests in certain regions (Puma *et al.* 2015; The Global Food Security Programme 2015). Due to climate change, such events may become more likely (Porter *et al.* 2014). Furthermore, the growing prevalence of certain crops in global food supplies has contributed to the increasing consumption of nutritionally poor food, some of which is highly processed (processed in a nutrient-poor manner), with serious consequences for human health (Khoury *et al.* 2014).

### 8.5.2 Human Health and land management

#### Health effects from mining

Adverse human health issues are also associated with mining and ore processing. While such operations generate employment and provide essential fuels and raw materials, residues such as lead affect air quality, posing a hazard especially to children, who are more likely to ingest such dust (Taylor *et al.* 2013b). The mining of some rare minerals, such as tantalum, often involves exploitation and even slavery (Gold, Trautrimms and Trodd 2015).

Mining waste is one of the world's largest waste streams by volume, with the potential to cause significant environmental impacts, including abrupt and extensive land use change (Sonter *et al.* 2014; Murguía 2015; Hudson-Edwards 2016; Sonter *et al.* 2017). The Global Waste Management Outlook (UNEP 2015) estimates mining waste to be in the order of 10-20 billion tons per year. Mining waste will probably continue to grow, since companies are now turning to lower-grade ores, which typically generate more waste per unit extracted. However, mining waste should also be regarded as a potential resource within a circular economy (Lèbre and Corder 2015). Mining activities generate impacts on ecosystems and lead to soil contamination. Toxic and radioactive dust emissions from mining waste are a relevant health issue in many parts of the world (see Chapter 5). Water pollution also results from mining (acid metalliferous drainage and leakages from tailing management facilities) (see Chapter 9) (Hudson-Edwards 2016). In many parts of Latin America, mining activities have an important impact. For example, artisanal gold mining in the Amazon basin deposited an estimated 3,000-4,000 tonnes of mercury during the late 1980s and early 1990s (Lacerda 2003). Although gold mining has shifted to different parts of the region, mercury contamination is still present in many soils and rivers as a result of land-use change (Lacerda, Bastos and Almeida 2012). This mercury also contributes to atmospheric pollution.

#### Waste and human health

The Global Waste Management Outlook indicates that cities generate between 7 and 10 billion tonnes of waste per year, figures that are expected to rise, even double, in lower-income African and Asian cities by 2030 (UNEP 2015). It also estimates that 3 billion people lack access to adequate waste disposal facilities, which poses health risks (infections, exposure to chemicals, dust) and generates environmental impacts (soil and water pollution, GHG emissions). An estimated 15 million people are operating globally as informal recyclers, many of them in dump sites (Binion and Gutberlet 2012). Identified health risks for these workers include exposure to chemical hazards, infections, musculoskeletal damage and poor mental health (Binion and Gutberlet 2012). Working in organized groups, such as recycling cooperatives in developing countries

(e.g. Bolivia and Colombia), has helped to reduce the domestic waste flow to landfills and improved the livelihoods of the recyclers (UNEP 2015). A key step towards reducing the environmental and health impacts of domestic waste is to shift from regarding waste as a health and environmental threat to including a resource management perspective, using waste as a source of raw materials (UNEP 2015).

#### Soil contamination

Soil health is essential for life, food security and the ecosystems services provided by soils. Many chemicals coming from industrial, urban and agricultural sources end up contaminating soils. In most developed countries, the main direct causes of site contamination are industrial and commercial activity. The extent of these sites can vary considerably, from small parcels of land to large industrial facilities or agricultural areas. Governments in the developed world maintain an inventory of contaminated and remediated sites. More than 2.5 million potentially contaminated sites are located in Europe, of which 342,000 are thought to be actually contaminated. About one-third of these have been identified, and more than 50,000 sites had been successfully remediated by 2014 (van Liedekerke *et al.* 2014). In the United States of America, the Superfund National Priorities list includes the sites contaminated with complex hazardous substances and pollutants (1,342 in 2016) that impact soil groundwater or surface water and that pose the greatest potential risks to public health and the environment (United States Environmental Protection Agency 2016). In Canada, more than 23,000 contaminated or suspected sites have been identified (Government of Canada 2017).

Developing countries are undergoing significant industrialization and urbanization. In large urban areas, provision of sanitation and drainage is needed as well as adequate governance so that urban waste is disposed of adequately (FAO and Intergovernmental Technical Panel on Soils [ITPS] 2015). Trace elements contaminate agricultural soil and crops in many Asian countries (Thangavel and Sridevi 2017). In many parts of Latin America intensive use of agricultural inputs contributes to soil contamination (UNEP 2010). In Africa, agrochemicals, mining, spills and improper handling of waste have contaminated soils (Gzik *et al.* 2003; Kneebone and Short 2010). In the Near East and North Africa, soil contamination is primarily the result of oil production and heavy mining.

#### Soil and human health

The burden of disease of soil-transmitted helminths – a group of parasitic worms including hookworm, ascariasis and trichuriasis/whipworm – is substantial, affecting human development and cognitive potential (Bartsch *et al.* 2016). These are generally acquired by walking barefoot on soil that has been contaminated by human faeces. High-intensity hookworm infection commonly affects both children and adults (Bartsch *et al.* 2016).

Land contains many trace elements, which enter the human food chain through the raising of crops and animals. Some are essential for good health (e.g. iodine, iron, selenium and zinc), while others are harmful in large quantities (e.g. arsenic and fluoride) (Oliver and Gregory 2015). Soils in mountainous areas often have reduced levels of iodine, and human populations in such areas can face higher health risks, as they are likely to

have reduced access to iodine-rich marine foods. Fertilizers are often contaminated by cadmium, which is not essential to human health and is harmful in high doses (Newbigging, Yan and Le 2015).

Positive effects of healthy soils in human health are related to nature's available benefits to people (FAO 2015d). For example, some valuable antibiotics have been derived from soil microorganisms (Oliver and Gregory 2015).

#### Food, chemicals and human health

Pesticides (defined here as also including herbicides) have generated an almost universal human exposure to synthetic chemicals, many of which are harmful and even fatal at high doses (Nicolopoulou-Stamati *et al.* 2016). However, there is much uncertainty concerning the health effects of chronic exposure to pesticides at lower doses. While human exposure to some chemicals, such as organochlorines, has reduced in recent years due to regulation, other synthetic compounds have entered the human food chain, such as other pesticides, artificial sweeteners and colorants. The health effects of these substances, whether in isolation or combination, are very difficult to determine for reasons including uncertainty concerning exposure, varying rates and times of the accumulation of these compounds and their release from human tissue, and the lag between exposure and disease. In 1990, the World Health Organization (WHO) estimated an annual 735,000 cases of specific chronic effects linked to pesticides globally (WHO and UNEP 1990), but pesticide use has increased dramatically since then, especially in developing countries where lax regulations and an absence of compliance mechanisms expose millions of farmers and workers to pesticides capable of causing chronic effects that include cancers; reproductive, respiratory, immune and neurological effects; and much more (Watts and Williamson 2015).

There is good evidence from high-income countries that groups occupationally exposed to pesticides, such as farmers, have higher rates of non-Hodgkins lymphoma, attributed to pesticides (Schinasi and Leon 2014). Higher than expected rates of Parkinson's disease have also been related to occupational exposure to pesticides (Liew *et al.* 2014). Other factors that influence health, such as age, undernutrition and impaired immune status, may also interact with the health effects of pesticides, but this issue is currently under-studied. The health effects of chronic pesticide exposures vary considerably on women and men due to their different physiologies. Data on pesticide use (and protection) by women and men in food production are incomplete and inconsistent. Overall, men are less sensitive than women to many pesticides (Hardell 2003; Watts 2007; Watts 2013). Pesticides and breast cancer rates have a strong connection (Watts 2007; Watts 2013) and women are more vulnerable than men to endocrine disruption from pesticides (Howard 2003). On the other hand, men are more sensitive to some (other) pesticides (Alavanja *et al.* 2003).

Food quality can also be impaired through biotic contamination, both microbiological and fungal (Gnonlonfin *et al.* 2013). Mycotoxins, including aflatoxins, can be generated when cereals are damaged by rain, both pre-harvest and through poor storage and are an important cause of liver cancer in many low-income settings (Wild and Gong 2010).

### 8.5.3 Tenure security

#### Land tenure, land deals

Despite heavy reliance on land resources, communities, especially in the global South, frequently lack ownership of the land they farm or hold in common. While high-impact scientific studies on the causal linkages between tenure security and food security are lacking (Ghebru and Stein 2013; Holden and Ghebru 2016; Lawry *et al.* 2017), there is sufficient evidence to show that food and energy security of local communities is profoundly diminished when they lose reliable access to their land resources (Godfray *et al.* 2010; Muchomba 2017; Tomei and Ravindranath 2018). Land and housing are the most important assets in large sections of the world. Secure rights, for both men and women, can help turn these assets into economic opportunities (Doss, Kieran and Kilic 2017). It also allows communities to tap into the benefits of institutional support and regulation (Dekker 2016). Indigenous populations, the poor, landless and women are among the most vulnerable to the repercussions of unequal landownership and access (Narh *et al.* 2016).

While the precise amount of community land in the world is unknown, estimates suggest that only approximately 10 per cent of formal land rights are registered or recorded worldwide (Veit and Reyta 2017). Estimates indicate that local communities and indigenous people depend on and manage 50-65 per cent of the world's land area (Alden Wily 2011; Pearce 2016), yet many governments still recognize their rights over only a fraction of these lands (Rights and Resources Initiative [RRI] 2015) (Figure 8.23).

Figure 8.23: Global forest ownership, 2002-2013 (%)

IP: indigenous peoples.

Source: RRI (2015).

As industrial agriculture and monoculture plantations have expanded, competition for land between industry, governments and communities has increased, putting pressure on forests and drylands, threatening local peoples' livelihoods in some parts of the world (UNCCD 2017). Without formal recognition and protection of their land rights, communities in some countries lack legal recourse following infringement of those rights. In the recent past, stories of poor governance have been under a global spotlight due to issues of land acquisition, land grabbing and land leasing amid fears of food scarcity and rising food prices. Although estimates vary, since 2000, between 26.7 million ha (Nolte, Chamberlain and Giger 2016) and 42 million ha (UNCCD 2017) of agricultural land around the world have become controlled by foreign investors. As of April 2016, Africa remains the most significant target area, with 42 per cent of all deals and 10 million ha (37 per cent) (Figure 8.24). Most deals involve the private sector, whose focus is on flexible crops. Importantly, food and biofuels produced on such land are unlikely to reach local communities.

Most acquisitions do not include domestic shareholders or local community negotiations, despite often targeting relatively highly populated areas dominated by croplands.

Studies have shown that lack of tenure security among local communities can translate into reduced investments in human capital (Dekker 2016), negative effects on land improvements (Eskander and Barbier 2017), reduced agricultural productivity (Place 2009; Lawry *et al.* 2014) and lower resilience in times of disaster risk (Unger, Zevenbergen and Bennett 2017).

There is increasing evidence of local indigenous communities successfully managing and conserving lands (Box 8.3). The World Resources Institute (Ding *et al.* 2016; Veit and Reytar 2017) indicates that 'tenure-secure' indigenous lands generate billions and sometimes trillions of dollars' worth of benefits in the form of clean water, erosion control, carbon sequestration, reduced pollution, and a suite of other local, regional and global ecosystem services (Figure 8.25).

Figure 8.24: Global maps of land deals, number of land deals per country (top), land deal area per country (bottom)

Source: Alexandratos and Bruinsma (2012).

### Box 8.3: Cultural values and conservation in Bhutan

Sustainable land management can be promoted by strengthening environment-friendly cultural values and customary institutions. In Bhutan, cultural values play a role in protecting ecosystem services. Mahayana Buddhism places strong significance on the peaceful coexistence of people with nature and the sanctity of life and compassion for others. This explains in large part the high share (71 per cent) of land area under forests in Bhutan and the fact that 25 per cent of Bhutan's population lives within protected areas (Nkonya, Mirzabaev and Von Braun 2016). Many of Bhutan's Buddhist monasteries are located within the forested landscapes of the country.

© Darshini Ravindranath

Figure 8.25: Benefits of tenure-secure lands outweigh the costs in three Latin American countries

Source: Ding et al. (2016).

Both the benefits and impacts can, however, vary by region and context due to the complex nature of defining and measuring land tenure. For instance, Eskander and Barbier (2017) find that, in Bangladesh, secure land tenure is associated with improvements in topsoil conservation. However, it is also related to lower human capital investments (e.g. lower spending on educational and recreational activities). Such heterogeneities in findings suggest that adequate attention needs to be given to the broader macro and sector conditions in addition to the local context within which tenure systems are governed.

At a global level, recommendations for stronger land governance in countries that are the targets of large-scale investments are becoming a priority. The rights of indigenous people to their lands and territories are explicitly mentioned in the United Nations Declaration on the Rights of Indigenous People (Article 25 and Article 26) (United Nations 2007).

The FAO *Voluntary Guidelines on the Responsible Governance of Tenure* (VGGT) also seek to improve the governance of land tenure with respect to all forms: public, private communal, indigenous, customary and informal (FAO 2012).

#### **Land and sociocultural services**

Land provides a variety of sociocultural and aesthetic benefits to people that are essential for sustainable, healthy livelihoods. Land degradation, deforestation and desertification lead to increases in land abandonment, outmigration and changes in rural power structures (due to increasing demand for intensification), among others. One of the key impacts of these changes has been a loss of critical sociocultural services provided by land, leading to a lowering of overall community resilience (Wilson *et al.* 2016; Wilson *et al.* 2017).

In many developing countries, most people reside in rural areas and are heavily dependent on land resources for their livelihoods. They grow crops for food and to sell in local markets; collect fodder for their livestock; gather wood for their stoves; and collect tree products for their health and well-being (Tomei and Ravindranath 2018). Here, the value of land is often an assertion of their long-standing sociocultural identity, place and heritage (Tomei and Ravindranath 2018). Kelly *et al.* (2015) show that ancient traditions such as festivals related to the preservation of timber, food and fuel resources reveal a deeply embedded relationship between land, culture and identity. In the European Union (EU), the recreational and cultural significance of land is incorporated, to an extent, through national and regional policies on management of ecosystem services. The EU 2020 Biodiversity Strategy, currently being implemented throughout Europe, predominantly covers 'cultural landscapes' (European Commission 2011; Plieninger *et al.* 2013).

Despite progress in recognizing these challenges, land-use trends and impact research continue to be dominated by the study of land-use change from the perspective of productivity, seldom acknowledging and documenting trends in the deep-rooted need for conservation from the perspective of communities (Sharmina *et al.* 2016).

#### **8.5.4 Gender inequality: land, health and food**

Existing gender inequality may contribute to increased poverty, people displacement, resource scarcity and other conflicts (Behrman, Meinzen-Dick and Qisumbing 2012; Verma 2014; White, Park and Mi Yong 2015). While progress has been made on the importance of incorporating women to sustain land productivity, it has often been at a superficial level (e.g. to meet certain global targets). Furthermore, women in agrarian societies often have a strategic role in reducing hunger, malnutrition and poverty as they play a central role in household food security, dietary diversity and children's health. Evidence suggests that women are much more likely than men are to spend income from these resources on their children's nutritional and educational needs (Malapit *et al.* 2015; Komatsu, Malapit and Theis 2018).

Agricultural contributions by women tend to be underestimated or not considered in official statistics since their focus is usually on formal employment in agriculture and on commercial agriculture. Women are usually engaged in subsistence agriculture, they tend home gardens and collect wild foods, and all these contributions are essential to food security (UNEP 2016a). In 2011, women represented 43 per cent of those economically active in agriculture (FAO 2011). However, they hold titles to less than 20 per cent of agricultural land (FAO 2010). In Africa, only Cape Verde can report that women own over half of agricultural holdings (50.5 per cent) (Doss *et al.* 2017). Few statistics show improvements in land tenure of women during the current decade, especially in countries of the global South (Figure 8.26).

Closing the gender gap in access to information and technology, and access to and control over production inputs and land, could increase agricultural productivity and reduce hunger and poverty (Croppenstedt, Goldstein and Rosas 2013).

#### **8.6 Policy responses**

Countless policies and actions attempt to address environmental degradation on land. Some strategies have been successful or are promising (e.g. restoration of degraded lands in specific locations such as the Great Green Wall Project in China – see chapter 15, sustainable management strategies such as no-tillage cultivation in Australia, payment for ecosystem services such as Mexico's National Program), while the benefits of others are not necessarily clear (e.g. the expansion of agricultural lands for flexible crop and biofuel production). However, most of these approaches do not consider the variety of benefits people obtain from land and focus only on its productive potential. Globally, land is becoming a scarce resource and is increasingly traded instead of being treated as a global common good due to its importance in the provision of basic services such as food production (Creutzig 2017). This section reviews this undesirable trend, while chapter 15 in Part B discusses in detail alternative land-use policies that could change this unsustainable trajectory.

Source: FAO (2017d).

### 8.6.1 Economic optimism and land degradation

Land degradation is a key global issue due to its adverse impacts on the environment, agricultural productivity and human welfare. The current paradigm of land management usually considers that the losses caused by land degradation and mismanagement can be compensated by increasing inputs in agriculture, expanding to new areas, and managing lands through command and control strategies such as replacing native forests with plantations (e.g. Chile, Indonesia). This approach also considers that nutritional and other associated social problems will gradually disappear as agricultural production expands (Rosegrant *et al.* 2001). However, social and environmental scientists warn that constantly improving agrotechnology may offer agricultural managers a false sense of security (Eswaran, Lal and Reich 2001).

Current trends are unlikely to supply future demands for food, energy, timber and other ecosystem services taking into consideration even moderate projections for land resources availability. By 2050, demand for food across all categories is likely to be 50 per cent more than today due to dietary changes associated with increasing incomes and population growth (Tilman *et al.* 2011; Alexandratos *et al.* 2012). At the aggregate level, yields are not increasing fast enough to meet demand without significant expansion of the agricultural area (Ray *et al.* 2012; Ray *et al.* 2013; Bajželj *et al.* 2014). This would be difficult to reconcile with large-scale afforestation or deployment of BioEnergy with Carbon Capture and Storage (BECCS) at the levels thought necessary to limit global warming to less than 2°C. For example, Smith *et al.* (2015) estimate that BECCS could require 380-700 million ha by the end of the century, representing up to 14 per cent of global agricultural land, for a 2°C pathway.

Continuing the current track it will be difficult to achieve the land degradation neutrality target adopted at the United Nations Conference on Sustainable Development (Rio+20) in 2012. Land degradation neutrality (LDN) is captured in SDG 15.3. Achieving land degradation neutrality by 2030 is regarded as critical for attaining other key international goals related to reducing biodiversity loss and deforestation, improving human welfare, and climate change adaptation and mitigation. Land-use change, a warmer climate, stagnating yields and unsustainable agricultural practices continue to lead to a reduced stock of organic soil carbon (Wiesmeier *et al.* 2016).

While scientists provide alarming estimates for the decline of productivity of lands globally and regionally due to soil erosion and desertification (Nkonya, Mirzabaev and Von Braun eds. 2016), many economists still believe that if land degradation were a severe issue, market forces would have taken account of it (Utuk and Daniel 2015). In other words, agricultural managers would not let their lands degrade to the point that it affects their incomes (Wiebe 2003). Cumulative productivity losses due to land degradation appear economically acceptable for most agricultural actors. In many instances, farmers can rely on government agricultural policies (e.g. subsidies for inputs and machinery) to curb losses associated with land degradation (Jat, Sahrawat and Kassam 2013).

However, these policies are not sustainable in either developing or developed countries. Market fluctuations of agricultural inputs could be more volatile than output prices. From 2005 to 2008, fertilizer prices rose much faster (by 400 per cent) than maize prices (by 100 per cent) and reached record high levels in 2008. In this case an input subsidy would be inefficient as

it would encourage unprofitable use of inputs (**Figure 8.27**) (Baltzer and Hansen 2011). The same study indicates that, in Malawi, the subsidy ratio jumped from 79 per cent to 91 per cent or from 3.4 per cent to 6.6 per cent of GDP in 2008-2009.

In sub-Saharan Africa (SSA), the contribution of fertilizer subsidies to national food security strategies remains highly controversial (Druilhe and Barreiro-Hurlé 2012). Success in the Asian Green Revolution was based on two main food crops grown under irrigation, wheat and rice. In SSA countries, yield response to fertilizer application is observed for some crops (e.g. maize), but not for most other staple crops grown in rain-fed areas (e.g. cassava, plantain, yam). In these contexts, fertilizer use is not profitable under market conditions, especially in some remote areas where output prices are too low. In order to be effective, agricultural programmes should be complemented with other government investments in infrastructure, education, health and rural development (Druilhe and Barreiro-Hurlé 2012) (**Figure 8.28**).

Reducing farm subsidies in rich countries would be positive for poor countries, although the effect will depend on their economic, trade and poverty characteristics (Boysen, Jensen and Matthews 2016). Meanwhile, the availability of subsidies in rich countries does not provide an incentive to adopt innovative soil conservation strategies.

For a long time, the market price of crops has been the standard for determining land-use policy. However, a new trend is being observed in growing competition between the financial and economic values of land. Land speculation and land grabbing can distort the actual economic value generated by land. With increasing land scarcity, the trend to consider land as a 'commodity' is only strengthened (ELD 2013). As land prices increase, more farmland will be sold to outsiders purely for speculative purposes. Consequently, lands might be left idle for some time, leading to less agricultural production, exacting a significant social cost if the practice becomes widespread.

In the EU, inflationary pressures are fueling land speculation and the acquisition of farmland. This rapid inflation has been attributed to the rise of 'new investors' in farmland, some with little connection to agriculture or farming. This process has

been termed by French activists as one of 'land artificialization': the loss of prime agricultural land, the expansion of cities, urban development, tourism and other commercial undertakings (Borras, Franco and van der Ploeg 2013). Land speculation and land 'artificialization' contribute to farmland concentration in the EU by raising the stakes and increasing the barriers for prospective farmers to take up farming (Kay, Peuch and Franco 2015).

One of the indicators of ever-increasing commoditization and commercialization of land was a recent boom for biofuel production. The relative abundance of cheap and suitable land in poor countries and increasingly liberalized trade and

**Figure 8.27: Fertilizer and maize prices, 2000-2010**

Prices are real US\$ indices of world market prices.

Source: Druilhe and Barreiro-Hurlé (2012).

investment regimes made them an attractive destination for farmland investments for biofuels (Schoneveld and German 2014). According to some experts, a boom of biofuel production was an important factor in the global food crisis in 2007-2008 (Chakraborty 2008).

### 8.6.2 Challenges for achieving the SDGs

Estimating the full economic benefits of land is neither easy nor straightforward (UNEP 2016b). The ecosystem services framework can contribute to comprehensive ecosystem assessments by dividing ecosystem services provided by land into categories that are interdependent and can be valued separately (Figure 8.29).

Current land management cannot prevent loss of natural capital while preserving ecosystem services (e.g. moisture retention, nutrient cycling), combating climate change (e.g. carbon sequestration), providing sustainable food production, addressing energy and water security, and promoting fair access to land (ELD 2013).

Intergenerational equity is not necessarily considered in current land management strategies, and present productivity gains are valued more than sustainable production for the future. Furthermore, land-use policy may not reflect the teleconnections that link production and consumption across the globe. According to current land policy approaches, most issues which cannot be addressed by increasing inputs are automatically dropped outside the land-policy domain. However, this approach is inappropriate as many social, gender, poverty and health issues are directly or indirectly associated with conventional ways of managing land resources and trading them across the globe.

Economic optimism plays in favour of enlarging farms due to their economic effectiveness and the difficulty of incorporating the economic impacts of the degradation of land resources. However, maximizing smallholders' potential, including women and indigenous peoples, is essential for food security and proper nutrition, and for reaching many SDGs. There are about 570 million farms in the world, and 84 per cent operate on less than 2 ha of land (International Food Policy Research Institute

**Figure 8.29: The provision of ecosystem services from natural capital: linkages between ecosystem services and human well-being**

Source: Millennium Ecosystem Assessment (2003).

[IFPRI] 2016). Small farms play different roles: billions of people get their income, employment and food from these lands. They are also home to most of the world's undernourished population. FAO estimates that if gender inequality in access to land resources is eliminated, agricultural output could increase by 2.5-4.0 per cent. Additionally, it would lead to a reduction of 12-17 per cent reduction in the number of undernourished people in developing countries (IFPRI 2016). In low-income agrarian societies, agricultural growth is more effective for reducing hunger and poverty than promoting any other sector of the economy (FAO 2015e). If SDG Target 2.3 is to be achieved by 2030, agricultural productivity of small farms should increase simultaneously with the incomes of their farmers. Policies should especially target the most vulnerable small-scale food producers (e.g. women, indigenous peoples), so they can have guaranteed access to market and other production means, including their material, informational and financial needs.

It is clear that minimizing food losses and waste will have significant environmental, social and economic benefits in supporting global food security (UNEP 2015). Where waste cannot be prevented, opportunities to recover value, such as conversion to compost, liquid fertilizers, biogas or higher value end-use products such as animal feed protein or biochemicals, should be explored (Jayathilakan *et al.* 2012; Nguyen, Tomberlin and Vanlaerhoven 2015; UNEP 2015). Achieving SDG Target 12.3 of halving per capita global food losses and waste at the retail and consumer levels and reducing food losses along production and supply chains, including post-harvest losses, by 2030, will require significant intervention and commitment, but also diverse strategies, since the reasons for food losses and waste, and the area within the food supply chain where losses and waste occur, differ between developed and developing countries (FAO 2015c).

# Chapter 9

## Freshwater

**Coordinating Lead Authors:** Erica Gaddis (Utah Department of Environmental Quality), Anna Maria Grobicki (Food and Agriculture Organization of the United Nations [FAO]), Rowena Hay (Umvoto), Gavin Mudd (RMIT University), Walter Rast (Meadows Center for Water and the Environment, Texas State University)

**GEO Fellows:** Beatriz Rodríguez-Labajos (Universitat Autònoma de Barcelona), Jaee Sanjay Nikam (Arizona State University)

## Executive summary

### **Freshwater mobilizes and amplifies the risks to human health and the environment associated with human activities**

(*established but incomplete*). The global water cycle integrates the impacts of population growth, agriculture, economic development, urbanization, industrialization, deforestation and climate change. All of these impacts affect freshwater quality and quantity. Hence, freshwater is now simultaneously a public good and a risk multiplier, affecting human and ecosystem health through pollutants and through climate change, which is intensifying storms, floods, droughts and desertification of land. Improved governance of every aspect of the water cycle is urgently needed in order to prevent, mitigate and manage these increasing risks. {9.2}

**The per capita availability of freshwater in the global water cycle is decreasing with population growth, coupled with the associated agricultural, industrial and energy requirements** (*established but incomplete*), while the continents are becoming drier in many places due to climate change impacts. {9.2}

**Increasing numbers of people are at risk of 'slow-onset disasters' such as water scarcity, droughts and famine. Such events sometimes lead to increased migration and social conflicts** (*well established*) {4.2}. The rising severity and frequency of water-related disasters pose growing risks to social and economic stability, as well as to ecosystems and their life-supporting ecosystem goods and services. There is evidence that water scarcity drives greater competition for available resources, reflected in food insecurity, prices and trade (*established but incomplete*). {9.2}

**Groundwater comprises a much larger freshwater volume than surface water. It is increasingly important for water security in many countries and regions** (*established but incomplete*). Some major aquifers at subregional and regional levels are threatened by poor management, resulting in unsustainable abstraction levels, groundwater pollution and issues of saline intrusion. {9.4}

**Approximately 1.4 million people die annually from diseases associated with pathogen-polluted drinking water and inadequate sanitation, with many millions more becoming ill** (*well established*). Some 2.3 billion people still do not have access to safe sanitation. The total global disease burden could be cut by up to an estimated 10 per cent with improved drinking water quality and access, sanitation, hygiene and integrated water resources management. {9.5}

**Human illnesses and deaths due to antibiotic- and antimicrobial-resistant infections are increasing rapidly and are projected to become a main cause of death worldwide by 2050** (*well established*). Antibiotics reach the aquatic environment from a wide range of sources, including treated and untreated human waste, agriculture, animal husbandry and aquaculture. Antibiotic-resistant bacteria are now found in both source water and treated drinking water worldwide. {9.5}

**New pollutants not easily removed by current wastewater treatment technologies are of emerging concern, including certain veterinary and human pharmaceuticals, pesticides, antimicrobial disinfectants, flame retardants, detergent metabolites and microplastics** (*well established*). Endocrine-disrupting chemicals are of particular concern as they are now widely distributed through the freshwater system on all continents. Their long-term impacts on human health include fetal underdevelopment, child neurodevelopment and male infertility. {9.7}

**Freshwater ecosystems are disappearing rapidly, representing a high rate of loss of biodiversity and ecosystem services** (*well-established*). Wetlands are the natural areas most affected by increasing urbanization, agricultural expansion and deforestation. Approximately 40 per cent of the world's wetlands were lost between 1997 and 2011, and this rate of loss continues. This is linked to an 81 per cent freshwater species population decline over the same period, the highest for any type of habitat (*likely*). The annual economic cost of wetland ecosystem losses between 1996 and 2011 was estimated at US\$2.7 trillion. {9.6}

**Peatlands (one type of wetland) store more carbon than all the world's forests combined** (*established but incomplete*). Climate change is thawing permafrost in boreal peatlands in and around the Arctic Circle, causing increased carbon emissions. Increased drainage and agricultural use of tropical peatlands cause wildfires and release significant quantities of carbon dioxide and methane as greenhouse gases. Altogether, about 15 per cent of peatlands worldwide had been drained by 2015, and currently contribute approximately 5 per cent of annual global carbon emissions. {9.6}

**SDG 6 water targets can be realized through engaging the public, private and non-governmental sectors, civil society and local actors in practising effective, efficient and transparent water resources governance** (*well established*). {9.9}

**Promoting water-use efficiency, water recycling and rainwater harvesting is becoming increasingly important to ensure greater water security and more equitable water allocation for different users and uses** (*well established*). {9.9}

**The agricultural sector, the largest consumer of freshwater globally, needs substantial improvements in water-use efficiency and productivity** (*well established*). The industrial and mining sectors also have strong potential for increasing water-use efficiency, recycling and reuse, as well as limiting water pollution. {9.9}

**Limited capacity currently exists to control long-term impacts of aquifer overabstraction and pollution in many locations** (*established but incomplete*). Monitoring, modelling and managing aquifer systems are essential to implement sound aquifer and integrated water resources management. Salinization of aquifers resulting from subsidence in river deltas is a complex catchment and coastal urbanization issue (SDG 11), but saline intrusion into coastal aquifers can be controlled by managed aquifer recharge (*well established*). {9.9}

**Efficient water use requires water-sensitive urban design of water infrastructure, including conjunctive surface and groundwater development and the promotion of managed aquifer recharge** (*well established*). Together with investment in wastewater treatment and recycling, these approaches support water quantity and quality management, and promote drought risk reduction and resilient urban water supplies. At the same time, the provision of drinking water supply and sanitation services to all, as well as leakage control from bulk water supplies, are still challenges in many cities worldwide. {9.9}

## 9.1 Introduction and priority issues

Freshwater is essential for the health and well-being of people, animals, plants, and aquatic and terrestrial ecosystems. The global water cycle is the most important component of weather and climate systems and it is accelerating because of climate change (**Figure 9.1**) (Stocker and Raible 2005; Huntington 2006; Organisation for Economic Co-operation and Development [OECD] 2016, pp. 5-6). The proportion of total freshwater that is readily available as surface water in rivers, lakes and wetlands is 0.4 per cent and decreasing dramatically. Increased floods and droughts (Huntington 2006) and the loss of glaciers (Gao *et al.* 2011; Yao *et al.* 2012; Rodell *et al.* 2018) result in direct and indirect impacts to human and ecosystem health (e.g. Holloway 2003, p. 2; Liu *et al.* 2005; Wang, Wang and Tong 2016; Liu *et al.* 2018).

Water is implicated in most of the Sustainable Development Goals (SDGs), being crucial to food security (SDG 2), health and well-being (SDG 3), energy security (SDG 7), sustainable

cities (SDG 11), responsible consumption and production (SDG 12), climate impacts (SDG 13), life below water (SDG 14) and terrestrial biodiversity (SDG 15). Most other SDGs are not achievable without adequate supplies of good quality freshwater (United Nations Water [UN-Water] 2016, p. 9). The sixth Global Environment Outlook (GEO-6) highlights links between water (SDG 6) and health (SDG 3). Degradation of water quality impacts human and ecosystem health (United Nations Environment Programme [UNEP] 2017). Nearly 1.7 million people die annually from preventable diarrhoeal diseases (Lozano *et al.* 2013; Sevilimedu *et al.* 2016, p. 637).

## 9.2 Pressures on freshwater

Multiple pressures on water resulting from the global drivers of environmental change (see chapter 2) are evident in the rapid deterioration in freshwater quantity and quality in different regions. This is exacerbated in certain regions by pressures from ongoing conflicts, human migration and the cumulative impacts of increasing frequency and severity of droughts,

**Figure 9.1: Global hydrological fluxes and storages (expressed in 1,000 km<sup>3</sup> per year), illustrating natural and anthropogenic cycles**

Source: Oki and Kanae (2006).

floods and storm surges (Intergovernmental Panel on Climate Change [IPCC] 2014). Impacts of natural and human-made disasters are compounded by unsustainable use of freshwater and related ecosystems, which reduces the resilience of the ecosystems (Sheffer *et al.* 2001; Holling and Gunderson 2002). Recent satellite data show that freshwater bodies are rapidly disappearing in many irrigated agriculture areas due to this combination of climate change and overabstraction (Rodell *et al.* 2018).

### 9.2.1 Climate change

The global water cycle is intimately tied to our changing climate. As the planet warms, the water cycle accelerates, with multiple changes in precipitation patterns putting pressure on freshwater ecosystems (Oki and Kanae 2006). The quantity of salt water is now increasing relative to freshwater due to global warming, land-use changes, melting ice and snow reserves, pumping of groundwater, drying of the continents, and rising sea levels (Bates *et al.* eds. 2008).

Many areas now receive less precipitation than in the past, while others receive more, with most regions experiencing increasingly unpredictable and variable temperature and precipitation patterns. Polar regions and high mountain regions are warming much faster than other parts of the world, with unforeseeable consequences (see Section 4.3.2). A 12 per cent increase in record-breaking high rainfall events occurred globally during 1981-2010 (Lehmann, Coumou and Frieler 2015). By contrast, there is evidence of increasing drought severity in Europe (Vicente-Serrano *et al.* 2014), with historical records indicating increased aridity over many areas since the 1950s (Dai 2011).

Global climate change interacts with weather and local-scale climate effects, as well as unsustainable water uses and diversions, leading to dramatic impacts such as shrinking freshwater bodies (e.g. Lake Chad, see **Box 9.1**; the Aral Sea; the disappearing wetlands of Islamic Republic of Iran [e.g. Lake Urmia] and the Iraqi Marshes; and even the Caspian Sea (Rodell *et al.* 2018)).

#### Box 9.1: Impacts of climate change on disappearing lakes and wetlands

Lakes and wetlands are important in regulating water cycles, for example by creating more moderate local climates (Kodama, Eaton and Wendler 1983; Laird *et al.* 2001; Saaroni and Ziv 2003; McInnes 2016; Dai *et al.* 2018). They warm up during the day and lose heat more slowly at night than the land surface, reducing temperature extremes in their basins. Through evaporation, they provide water vapour and precipitation during winter, and they cool and stabilize the local climate in summer. Urban wetlands have been shown to provide a local cooling effect of at least 1-3°C (Filho *et al.* 2017).

Climate change alters water cycles over lakes, wetlands and other standing (lentic) water systems, reducing the quantity of fresh water and waterbody surface area. A warmer climate increases evaporation over the waterbody and adjacent land, but a warmer atmosphere also takes more time to become saturated with water to subsequently produce rainfall. Thus, moisture evaporated from a waterbody may blow away before it can fall as rainfall in its own basin. The basin then becomes drier, with less run-off into the waterbody and associated rivers and wetlands, increasing the need for agricultural irrigation water. These factors collectively accelerate the shrinking of a waterbody, as illustrated in the case of Lake Chad (below), which has lost 90 per cent of its surface area, with an enormous loss of its associated biodiversity, especially fish, and loss of livelihoods for the millions of people dependent upon the lake. Human water use is estimated to account for 50 per cent of the shrinkage and climate change for the remainder (Coe and Foley 2001; Gao *et al.* 2011). The resulting change in microclimate establishes a cycle that further contributes to the drying and desertification of the continent and intensifies the impacts of global climate change.

Figure 9.2: Shrinkage of Lake Chad

Sources: Hansen *et al.* (2013); Guzinski *et al.* (2014).

Too much rainfall brings pollution, soil erosion, avalanches and mud slides which, together with floods, tornadoes and cyclones, are responsible for much physical damage to infrastructure, loss of life and injury. Too little rainfall causes drought, extreme wildfires, sandstorms, soil degradation and increased competition over water sources, often leading to the accelerated shrinkage and loss of these goods. Collectively, these realities and risks have grave socio-political, economic, environmental and ecological implications, making better management and governance of freshwater resources an imperative.

### 9.3 Water and land use

Growing cities and agricultural intensification are increasingly depleting both surface water and aquifers. Wetlands are being drained, and many rivers, lakes and ponds are vanishing in water-scarce regions. Land-use changes result in surface hardening of natural areas, reducing infiltration and aquifer recharge, while increasing water run-off and pollution. Land degradation and deforestation also cause increased run-off, carrying eroded sediment through rivers into oceans (see Section 8.4.2). In areas experiencing large-scale deforestation, the likelihood of precipitation events is decreasing and soil erosion is increasing (Birkinshaw *et al.* 2011; Ellison, Futter and Bishop 2012).

Agriculture is responsible for an average 70 per cent of global water withdrawals (UN-Water 2017). Industrial processes and energy generation increasingly compete with agriculture and cities for available water. However, much energy water demand is for non-consumptive uses (e.g. cooling) (UNEP 2012a).

The interconnections between water, energy security and food security have identified tensions and trade-offs between them requiring careful scrutiny and consideration (Rosengrant *et al.* 2009). This nexus becomes especially important when considering drivers such as urbanization, population, economic growth, technology and innovation (Bleischwitz *et al.* 2018).

### 9.4 Global state and trends of freshwater

#### 9.4.1 Water quantity

Geographic variations, coupled with climate change, result in uneven distribution of rainfall and freshwater sources, with deserts and rainforests highlighting these water availability extremes (Figure 9.1 and Figure 9.4). Groundwater is the major drinking water source for the majority of people globally, particularly in arid regions and during drought. The estimated available renewable groundwater resource in Africa is more than 100 times that of total annual renewable surface-water resources (MacDonald *et al.* 2012, p. 5). However, deeper aquifer water is constrained by exploration and abstraction costs. Abstraction of very ancient 'fossil groundwater' is unsustainable, because this is not a renewable resource.

#### 9.4.2 Water withdrawals

Human and environmental water demands vary spatially and culturally across rural and urban areas. While an average of 70 per cent of water withdrawals worldwide are for the agricultural sector, this varies widely across regions and countries (Hoekstra and Mekonnen 2012, p. 3232; Food and Agriculture Organization of the United Nations [FAO] 2016;

UN-Water 2017). South-East Asia uses more than 80 per cent of its available freshwater for agriculture (FAO 2016).

The North American region has the highest per capita freshwater use (Hoekstra and Mekonnen 2012, p. 3232; UNEP 2016a, p. 71), although increased water-use efficiency is helping to lower demand, despite population and economic growth (UNEP 2016a, p. 71). Water withdrawals by all sectors in the United States of America (Figure 9.3) illustrate high water usage for cooling in electricity production.

Groundwater is increasingly important globally, representing estimated withdrawals of about 982 km<sup>3</sup> (Margat and van der Gun 2013), equivalent to nearly 33 per cent of total water withdrawals (Seibert *et al.* 2010, p. 1863; Famiglietti 2014, p. 945). Since conventional groundwater withdrawal technology is easily accessible to landowners, extraction is highly decentralized. Groundwater in confined artesian basins (Bundesanstalt für Geowissenschaften und Rohstoffe [BGR] 2008) can be accessed at depths of up to 2 km, and often provides a strategic water resource, especially during droughts (e.g. Great Artesian Basin, Australia [GABCC] 2016); Table Mountain Group, South Africa) (Hay and Hartnady *et al.* 2001; Weaver *et al.* 2002; Blake *et al.* 2010).

Industries that abstract from aquifers include industrial agriculture, mining, geothermal energy and ground-source heat pumps, disposal and/or storage of hazardous wastes (e.g. landfills, nuclear waste), fluid injection (e.g. oil and gas extraction through hydraulic fracturing or 'fracking' and associated wastewater reinjection), and underground construction activities. Such pressures are leading inexorably to stronger competition/interactions between the different industries, with sometimes unforeseen consequences.

Figure 9.3: United States water withdrawals from all sources (1950-2010)

Note: 1 billion gallons = 3.8 million m<sup>3</sup>.

Source: Maupin et al. (2014, p. 46).

Figure 9.4: Global hydrogeological map illustrating various aquifers and groundwater resources

Source: BGR and United Nations Educational, Scientific and Cultural Organization [UNESCO] (2008).

Figure 9.5: Global trends in increasing groundwater use

Source: Shah (2014, p. 12).

Groundwater use has plateaued in some regions but is increasing elsewhere (Figure 9.5), such as in Asia and the Pacific and West Asia (e.g. about two-thirds of freshwater utilized in West Asia). About 75 per cent of European Union (EU) inhabitants rely on groundwater for drinking (European Commission 2008, p. 7), and groundwater use, compared with surface water, has increased substantially to 1.3 trillion m<sup>3</sup> per year across North America (Famiglietti and Rodell 2013, p. 1301). Groundwater accounts for 30 per cent of water withdrawals in Latin America (Campuzano *et al.* 2014, p. 38) and an estimated 75 per cent of the African population depends on it (Altchenko and Villholth 2013, p. 1498). It must be noted, however, that estimates of groundwater withdrawals and use vary widely, constituting a critical data gap.

Increased agricultural groundwater use has led to rising depletion rates in major aquifers in arid and semi-arid zones (UNEP 2012b). Pumping rates that for decades have exceeded long-term natural recharge have resulted in some larger aquifers being 'mined' unsustainably (Famiglietti 2014, p. 946). Five of the world's seven largest aquifers are in Asia and the Pacific, and are overstressed (UNEP 2016b, p. 84).

Excessive groundwater abstraction has caused land subsidence in some coastal cities (e.g. Bangkok; Ho Chi Minh City; Jakarta; Manila) (UNEP 2016b, p. 87). Overexploitation of an aquifer can also impact wetland ecosystems. Hydraulic fracturing (fracking) for oil and gas extraction merits concern for its groundwater impacts (see Box 9.2). Groundwater is often underexplored on some islands due to surface-water availability, while other islands can be wholly reliant on it. Climate change impacts may lead to a greater reliance on and pose a threat to ground water because of sea level rise. Further studies are needed since islands are experiencing increasing freshwater shortages (Famiglietti 2014, p. 946).

#### 9.4.3 Glacial retreat

Climate change is affecting regional water availability around the world, especially in areas reliant on glacial meltwater. Rivers originating in the Hindu-Kush Himalayas are among the most meltwater-dependent systems, and the source of ten large Asian river systems (Amu Darya, Brahmaputra, Ganges, Indus, Irrawaddy, Mekong, Salween, Tarim, Yangtze, Yellow), providing water for 20 per cent of the world's population (UNEP 2016b, p. 81) (Figure 9.7).

## Box 9.2: Water quality impacts of mining

Modern mining generates large volumes of tailings (finely ground rock remaining after extracting ore) and waste rock (non-mineralized rock; low-grade ore), often containing iron sulphide minerals (e.g. pyrite). Exposed to the surface environment, these can react with water and oxygen to form sulphuric acid, producing acid metalliferous drainage (AMD). AMD can degrade water quality and impact aquatic biodiversity. Recent tailings dam failures (e.g. Mount Polley, Canada; Samarco, Brazil) demonstrate that mine wastes escaping into the environment can also significantly impact aquatic ecosystems and biodiversity, with tailings particles smothering riverbeds, reducing light penetration and oxygen levels, and affecting river geomorphology (Mudd *et al.* 2013).

**Figure 9.6: Examples of surface streams affected by acid and metalliferous drainage (AMD) and/or tailings discharges: (left) Urban stream severely affected by AMD in western Witwatersrand Basin, Johannesburg, South Africa; (right) Tailings sediment from Samarco Dam**

**Figure 9.7: Rivers originating in the Hindu-Kush Himalayas are among the most meltwater-dependent systems**

Sources: UNEP and Global Environment Facility [GEF] 2018; Global Land Ice Measurements from Space [GLIMS] 2018.

Figure 9.8: Retreat of Quelccaya ice cap in Peru between 1988 (left) to 2010 (right)

Source: Schoolmeester *et al.* (2018).

Tropical glaciers in the Andes account for more than 80 per cent of available freshwater for downstream populations and ecosystems in Latin American semi-arid tropic regions (UNEP 2013, p. 1). These are melting at an accelerating rate attributed to climate change (Chevallier *et al.* 2011; Rabatel *et al.* 2013), raising concerns about sustainable water supplies (**Figure 9.8**). Glacial retreat in the European Alps has accelerated over the last two decades (Huss 2012, p. 1132), while Central Asian glaciers have lost 27 per cent of their mass and 18 per cent of their area (Farinotti *et al.* 2015, p. 720; Yao *et al.* 2012).

#### 9.4.4 Water scarcity

Water scarcity is defined as less than 1,000 m<sup>3</sup> per capita of available, renewable freshwater per year (United Nations World Water Assessment Programme [WWAP] 2012, p. 124). The differentiation between areas of economic water scarcity (where storage, treatment and conveyance infrastructure are lacking) and absolute or physical water scarcity is illustrated in **Figure 9.9** (WWAP 2012).

Sustainable freshwater supplies from surface and groundwater sources are critical for human and ecosystem needs, and for achieving the SDGs. Excessive withdrawals are often the cause of water scarcity. Lack of infrastructure, combined with rapid population growth, can lead to economic water scarcity, although there is not always agreement about the cause of water scarcity being physical, economic or indeed political in nature. Water of appropriate volume and quality is not always available at the right time or in the right place for a specific use.

Water scarcity is common throughout West Asia and the Asia and the Pacific region, and in arid parts of Africa, Latin America, the western United States of America and the Middle East. Factors that typically stress water resources include large populations, agricultural expansion and intensification, rainfall variability, rapid development, increasing urbanization, industrialization and climate change. The desiccation of the Aral Sea in Central Asia remains one of the most dramatic water-related environmental disasters of the 20<sup>th</sup> century. Most global climate model projections predict a 20 per cent rainfall

decrease over the next 50 years in West Asia, with increased temperatures, evaporation and relative humidity all influencing water availability (UNEP 2016c, p. 12).

Desertification is a pressing problem in Africa's sub-Saharan region, arising from climate change and internal migration (UNEP 2016d). Although physical and economic water scarcity prevails across Africa, its surface- and groundwater resources are considered underdeveloped, in terms of meeting human livelihood and development needs (UNEP 2016d). In this context, many small- to medium-scale water infrastructure projects are well suited to local water demand.

In parts of the developed world (e.g. Europe, North America, Australia), water scarcity is a challenge that is commonly addressed through large water infrastructure projects, such as dams, long-distance pipelines and desalination plants. Given expected population growth trends, regions such as the Middle East, Africa and Asia need to address water scarcity in innovative and scale-appropriate ways, including water governance, rainwater harvesting and wastewater recycling, leapfrogging the conventional solutions of the past.

### 9.5 Water quality

Although natural processes also generate water pollutants, human activities related to population growth, urbanization, agricultural expansion, transportation, and human and industrial waste discharges are typically the main sources of water pollution (UNEP 2016e). They include pathogens, nutrients, heavy metals and organic chemicals (Annex 9-1) from point sources (domestic, industrial or sewage pipeline discharges; septic tank leakage) and/or catchment non-point sources (land surface run-off from extensive diffuse agricultural use and urban areas following rainfall and snowmelt events).

Water quality in many Latin American, African, Asian and Pacific rivers has generally decreased since the 1990s, although the majority are still in relatively good condition (UNEP 2016e). Water quality in many European rivers has improved since adoption of the EU Water Framework Directive

Figure 9.9: Global physical and economic water scarcity

Source: WWAP (2012, p. 125).

in 2000. About half of United States waters do not meet standards protective of aquatic life, with more than 40 per cent not meeting recreational-use standards (UNEP 2016a). The water quality of many lakes and reservoirs is particularly endangered worldwide because of their long water residence times and tendency to accumulate pollutants (International Lake Environment Committee Foundation [ILEC] and UNEP 2016).

Groundwater pollution sources include non-point agricultural and urban run-off, on-site wastewater treatment, oil and gas extraction and fracking activities, mining, and industrial sources (Foster *et al.* 2016). Natural contamination occurs in some cases (e.g. sodium-chloride salinity, arsenic, fluoride,

radioactivity in fossil groundwater aquifers). Human health impacts from untreated groundwater are of particular concern (Morris *et al.* 2003; UNEP 2016e).

#### 9.5.1 Pathogens

Water-borne diseases remain major challenges in many African, Asian, Pacific and Latin American cities and rural communities (Annex 9-1). Although collection and treatment of human excrement has largely curtailed the problem in developed countries, sewage outfalls still generate large pathogen loads. However, parasites can survive waterbody conditions for many weeks, while viruses may survive drinking water treatment.

© Shutterstock/clicksabhi

Pathogens remain a major cause of human death and illness, particularly in developing countries ([http://www.who.int/water\\_sanitation\\_health/takingcharge.html](http://www.who.int/water_sanitation_health/takingcharge.html)). High child mortality, for example, is associated with diarrheal diseases from contaminated water in Africa, Asia, the Pacific and Latin America (Annex 9-1). Principal pathogen sources include inadequately treated human and livestock wastes, and combined sewer overflows and leaks. **(Figure 9.10)**

Irrigation with inadequately treated or diluted wastewater occurs in many developing countries, increasing agricultural productivity for many poor communities, but often at the expense of human health and environmental risks. Comparison studies highlight environmental degradation and higher water-borne disease rates in wastewater-irrigated areas (75 per cent prevalence rate for gastroenteritis in children 8-12 years of age, compared with 13 per cent in freshwater-irrigated areas) (Grangier, Qadir and Singh 2012).

Antibiotic and antimicrobial resistance is a major global health concern, with the spread of resistant bacteria and resistance genes in the environment being a critical component of integrated control efforts (Berendonk *et al.* 2015). The major source remains human and animal excreta, with aquaculture increasingly adding to the levels in the water environment (Kümmerer 2009). The World Health Organization (WHO) predicts antimicrobial resistance to become a major cause of deaths globally by 2050 (Annex 9-1). Wastewater-treatment plants have diverse abilities to remove antibiotic-resistant bacteria, and limited capacity to remove antibiotic drugs (Pruden *et al.* 2013; Berendonk *et al.* 2015).

### 9.5.2 Nutrients

Eutrophication represents the natural ageing process of lakes and wetlands, wherein they become enriched with nutrients and sediments, becoming more biologically productive, usually over a long period (Annex 9-1). Human activities can greatly increase these nutrient loads, accelerating this process, with

detrimental effects on the whole ecosystem. The resulting algal blooms and aquatic plant growths interfere with many human water uses and can greatly affect the balance and diversity of aquatic flora, fauna and algal species (OECD 1982; Research Center for Sustainability and Environment-Shiga University and ILEC 2014). Major nutrient sources include inadequately treated domestic sewage discharges, urban and agricultural run-off, aquaculture and mariculture. Algal blooms can turn lakes, reservoirs and slow-moving rivers turbid and green in colour, depleting the water's oxygen content when algae die and undergo decomposition. Some blue-green algal species are toxic to fish and livestock (O'Neil *et al.* 2012) and affect human health. A clear relationship between climate change and eutrophication of lakes has also been reported (Jeppesen *et al.* 2010).

More than half of the total phosphorus loads in the five UN Environment regions originate from inorganic agricultural fertilizer run-off **(Figure 9.11)**. Livestock waste used as fertilizer can also be problematic because its nitrogen-phosphorus ratio is higher than that needed by crops, thereby potentially saturating soils with phosphorus, which can then reach waterbodies via non-point source run-off. River nutrient contributions to coastal areas almost doubled during 1970-2000 (Annex 9-1). The Gulf of Mexico exhibits a 'dead zone' typically covering nearly 13,800 km<sup>2</sup> attributed to nitrogen from grain fields in the midwestern United States of America carried down the Mississippi River, with eventual decay of the algal growth consuming the oxygen in the water, suffocating marine life. There are nearly four times as many dead zones (400) in the oceans now as there were in 1950, including in the Mediterranean Sea (Pearce 2018).

Some major urban areas in Asia and the Pacific experience groundwater nitrate concerns from sewer and septic tank leaks (Umezawa *et al.* 2009), and rural areas in many countries are affected by excessive chemical fertilizer application (Novotny *et al.* 2010). The effects of nitrates in groundwater has long been a public health concern, particularly as a causative factor in methemoglobinemia in infants ('blue baby' syndrome).

**Figure 9.10: Model estimates of trends in faecal coliform bacteria levels in rivers during 1990-1992 and 2008-2010**

Orange or red river stretches indicate increasing concentrations between these periods; red river stretches indicate increasing trends of particular concern.

Source: UNEP (2016e).

Although over half of EU surface waters improved during 1992-2010 (average river phosphate and nitrate levels decreasing by 57 per cent and 20 per cent, respectively), many still do not meet European Water Framework Directive environmental objectives (European Union 2000).

### 9.5.3 Sediments

Sediments result from erosion of exposed soil surfaces, with much eroded soil being deposited in basins throughout the world, including in Africa, Asia and Latin America. Deforestation, poor agricultural and livestock practices, intensive fuelwood harvesting, mining, urbanization and unplanned settlements are major causes of soil vulnerability to erosion, and storm-generated run-off carries soil into downstream waterbodies (Annex 9-1). Sediment-associated pollutants can have human health impacts, and interfere with water uses and aquatic organism metabolism and habitats (UNEP 2017). Artificial channels from dams and urban development can change sediment flow paths, lead to erosion and reduce sediment available to build up banks, river deltas and beaches along coastlines, causing aquatic ecosystem changes (Blum and Roberts 2009, Syvitski *et al.* 2009; Yang *et al.* 2011; Cloern and Jassby 2012; Adams *et al.* 2016; Yihdego, Khalil and Salem 2017).

### 9.5.4 Organic pollutants

Biodegradation of organic pollutants such as liquid manure, sewage effluents and sewage treatment sludge can deplete oxygen concentrations in waterbodies, causing fish kills and releasing heavy metals from bottom sediments back into the water column, a process characterized by a high biochemical oxygen demand (BOD) from microbial decomposition of these

pollutants. Algal bloom decomposition also can deplete the oxygen content in eutrophic waterbodies, particularly lakes and wetlands.

Based on model analyses, BOD concentrations increased in many parts of Africa, Asia and the Pacific, and Latin America during 1990-2010 from industrial and domestic wastewater discharges, and agricultural and urban run-off, with highest increases in rapidly urbanizing and industrializing countries (Annex 9-1). BOD pollution in most developed countries has significantly decreased with enhanced wastewater treatment (e.g. implementation of the 1991 EU Urban Wastewater Treatment Directive).

Synthetic organic pollutants include pesticides, industrial chemicals and solvents, and personal care and pharmaceutical products. Persistent organic pollutants (POPs) are particularly problematic because they do not readily biodegrade in the aquatic environment. Used in many industrial and agricultural applications, they can impact human health and aquatic ecosystems, persisting in fatty tissues of humans, fish and other organisms, and accumulating in sediments. DDT has human carcinogenic and teratogenic risks, for example, but is still used in many regions to control malaria (Annex 9-1). Other synthetic compounds, including non-POPs, continue to enter the ecological food chain globally, while others, such as endocrine-disrupting chemicals, are considered contaminants of emerging concern (see Section 9.5.7). Neonicotinoid and fipronil systemic insecticides, for example, are water soluble and can leach into freshwater and marine systems. Neonicotinoid insecticides are toxic to most arthropods and invertebrates, while fipronil is toxic to fish and some bird species (Annex 9-1; van Lexmond *et al.* 2015; Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services 2017).

**Figure 9.11: Sources of anthropogenic total phosphorus loadings to lakes (five largest lakes by surface area in each of the five UN Environment regions), showing average percentage contributions in 2008-2010 annual loads**

Source: UNEP (2016e).

### 9.5.5 Heavy metals

Used in a range of industrial and agricultural sectors, heavy metals exhibit widespread environmental distribution. Heavy metals from industrial activities, and large-scale and artisanal mining, have seriously degraded water in some Asian, Pacific and South American countries (Da Rosa *et al.* 1997; Spitz and Trudinger 2008; Sikder *et al.* 2013; Annex 9-1). They can bioaccumulate in plants grown with contaminated irrigation water (Arunakumara, Walpola and Yoon 2013; Lu *et al.* 2015). Many (mercury, lead, chromium, cadmium) are toxic to humans and aquatic organisms (Kim *et al.* 2017).

Heavy metals associated with water-intensive mining are problematic in Africa and Latin America (Annex 9-1). Water drainage from active and abandoned mines can cause significant water degradation (e.g. mercury and arsenic used in gold mining can pollute surface and groundwater). Examples of untreated mine-water discharging into streams and rivers include Mount Morgan (Australia) and Tisza River (Hungary), where reservoirs, agricultural irrigation water and aquatic ecosystem biodiversity have all been degraded. Groundwater pollution also has been reported to have occurred in Alberta, Canada because of the tar sands industry (Timoney and Lee 2009).

Groundwater contamination with naturally occurring arsenic occurs in South Asia and other countries in Asia and the Pacific (Rahman, Ng and Naidu 2009; Annex 9-1). Arsenic mobilization can also be facilitated or worsened through such human activities as metal mining and groundwater abstraction and, in some cases, through use of arsenic-based pesticides in agriculture and wood preservation. Although some problems remain, heavy metal contamination has generally diminished in EU countries since 2000. A dramatic example of heavy metal contamination involved Flint, Michigan (United States of America). A decision to switch the city's drinking water

supply in 2014 from Lake Huron to the Flint River, containing more corrosive water, released lead from leaded pipes in the city's water distribution system, with significant human health impacts (Masten *et al.* 2016).

### 9.5.6 Salinity

Increases in salinity, a measure of the quantity of dissolved minerals in freshwater, result from land-use changes, agricultural irrigation drainage, lake evaporation and seawater intrusion, usually most severe in arid and semi-arid regions (Vengosh 2003). Excess salinity renders the water unfit for many human uses, and most freshwater organisms have limited salinity tolerance (UNEP 2016e).

Salinity problems persist at various degrees in rivers throughout Africa, Asia and the Pacific, and Latin America, affecting agricultural irrigation as a result of accumulation of naturally occurring minerals in irrigation water, as well as industrial water uses (Foster *et al.* 2018; Annex 9-1), with surface-water salinization being a major issue in Central Asia. Saline water intrusion into coastal aquifers can result from over-abstraction and mismanagement, as well as sea level rise. Apart from sodium, waters with elevated levels of magnesium are emerging examples of water quality deterioration leading to environmental and food security constraints in several irrigation schemes (Qadir *et al.* 2018).

### 9.5.7 Contaminants of emerging concern

Water contaminants of emerging concern include certain human and veterinary pharmaceuticals, personal care products, insect repellents, antimicrobial disinfectants, flame retardants, detergent metabolites, microplastics and manufactured nanomaterials ('nanoparticles') (Figure 9.13; Kolpin *et al.* 2002; UNESCO 2016; Yuan *et al.* 2018). The United States Geological Survey detected such contaminants in a

**Figure 9.13: Source and pathways of pharmaceutical and personal care products (PPCPs) entering surface and groundwater, highlighting need for improved detection of commonly found PPCPs and their transformative products**

Source: Adapted from Petrović *et al.* (2003); Mompelat *et al.* (2009); Yang *et al.* (2017).

majority of sampled streams in the United States of America (Annex 9-1; Kolpin *et al.* 2002). They also were detected in all pan-European seas, as well as groundwater (Sui *et al.* 2015; Corada-Fernández *et al.* 2017). Used in fire retardants, oil and water repellents, furniture, waterproof clothes, takeaway containers and non-stick cookware, poly- and perfluoroalkyl substances (PFAS) were found in water systems serving 16 million people in 33 states in the United States of America between 2013 and 2015 (INTJ Input 2017). Conventional wastewater treatment is not effective in removing most of these contaminants from domestic and industrial wastewaters.

Many are endocrine-disrupting chemicals (EDCs), attributed partly to wastewater treatment plant overflows, particularly those with combined sewer systems. Being found in site-specific studies in Europe, the Asia and the Pacific region, Canada and the United States of America (Annex 9-1; Sui *et al.* 2015), their long-term human health impacts

include fetal underdevelopment, child neurodevelopment and male infertility (Meeker 2012).

Micro- and nanoplastics (manufactured nanomaterials) resulting from microplastics in cosmetics, fragmentation of large plastic waste, tyre wear particles and laundering of synthetically based clothes are increasingly affecting freshwater and marine ecosystems (Annex 9-1; Horton *et al.* 2017). Of the 275 million (metric) tons of plastic waste generated by 192 countries in 2010, an estimated 4.8-12.7 million tons ended up in the oceans because of inadequate solid waste management. They are found worldwide in fresh and ocean waters, river and delta sediments, and in the stomachs of organisms ranging from zooplankton to whales (UNEP 2016g). Microplastics also can contain and absorb toxic chemicals. Electronic wastes also are of increasing concern because of their widespread abundance and unknown risks to surface- and groundwater quality.

### 9.5.8 Other water quality concerns

Groundwater pollution from oil and gas fracking activities, which use large quantities of chemicals and discharge large volumes of 'produced water', is problematic in the Americas (Osborn *et al.* 2011; Vengosh *et al.* 2014; Annex 9-1). Heavy metals, particulate matter, various organic chemicals, and EDCs are widely used in, or become by-products of, these oil and natural gas operations (Webb *et al.* 2017).

Lake acidification from atmospheric deposition of fossil fuel emissions causes problems in areas lacking soils or bedrock capable of buffering the emissions, including the north-east United States of America, south-east Canada and some Scandinavian regions. The situation is improving for affected lakes in the Adirondack Mountains region of the north-eastern United States of America, where sulphur and nitrogen oxide emissions have decreased since the 1970s (Annex 9-1; Driscoll *et al.* 2016).

Thermal pollution and radionuclides also represent water quality concerns. Thermal pollution, often resulting from using freshwater as a coolant in power plants and industrial manufacturing activities, can degrade water quality by changing ambient water temperature. The impacts can be multiple, including reducing the dissolved oxygen concentration while at the same time increasing the respiration rates of aquatic organisms using it. Some aquatic species populations may decrease because they cannot thrive or reproduce in waters at higher temperature, while others may increase, potentially changing the overall ecosystem dynamics of a waterbody. Radioactive contamination typically in the form of accidental releases of radionuclides from nuclear activities have polluted inland freshwater systems in some areas, with negative implications for aquatic and other organisms, including humans, using these waterbodies (Echols, Meadows and Orazion 2009).

## 9.6 Freshwater ecosystems

### 9.6.1 Continuing loss of wetlands

Freshwater ecosystems (or inland wetlands) include marshes, swamps, peatlands, wetland forests, rivers, lakes, ponds and headwaters. They provide a range of provisioning, regulatory and supporting ecosystem services, including water and food supply, fodder and building materials, carbon and nutrient sequestration, unique habitats for endangered species (including migratory birds), flood- and drought-buffering capacity, ecotourism and cultural services (WWAP 2018). Although freshwater ecosystems only cover 0.8 per cent of Earth's surface, they support approximately 10 per cent of all known species (World Wide Fund For Nature [WWF] 2016), and are among the world's most biodiverse habitats. They are the ecosystems most affected by changing land use, particularly increasing urbanization and agricultural expansion.

Between 69 per cent and 75 per cent of wetlands worldwide are estimated to have been lost since 1900 due to rapid population growth, urbanization and agricultural expansion (Davidson 2014). The extent of the loss since 1970 differs notably across regions, the slowest loss rate being apparent in Oceania and North America. Levelling off of the loss rate in North America is due partly to the current national policy of "no net loss of wetlands" in the United States of America (United States Fish and Wildlife Service 1994). Although constructed wetlands can compensate to some degree for some natural wetland removal, they cannot typically provide the same level of ecosystem functioning, resilience and biodiversity, emphasizing the need for natural wetland protection and conservation (see Section 9.4).

Ecosystem services for all wetland types have been valued financially across a very wide range from US\$300-US\$887,828 per hectare per year, with a median value of US\$12,163 (de

Groot *et al.* 2012). More specific assessments are needed. A recent valuation of swamp and floodplain ecosystem services attributed an average annual global value of US\$25,000 per hectare per year, excluding the value of the land itself (Costanza *et al.* 2014). The estimated annual loss to the global economy from diminishing swamp and floodplain areas from 165 to 60 million ha between 1997-2011 is US\$2.7 trillion (Costanza *et al.* 2014).

Although covering only 3 per cent of the planet's land surface, peatlands have a high carbon-sequestration value, hence they contain more carbon than all global forest biomass combined (Joosten 2015). The world's largest tropical peatland (Cuvette Centrale) covers an area of 145,500 km<sup>2</sup> in the Congo River basin, containing an estimated 30 gigatons of carbon accumulated over the past 11,000 years (Dargie *et al.* 2017). Draining peatland areas for agriculture (e.g. the large Indonesian and Malaysian palm oil plantations) breaks down the peat, rapidly emitting carbon as CO<sub>2</sub> and methane. About 15 per cent of peatlands worldwide have been drained in the last 40 years, contributing approximately 5 per cent of global carbon emissions (Joosten 2015).

As the drained peat decomposes quickly, it dries out, shrinks and subsides. Tropical coastal peatlands are subsiding by an average 5-7 cm/year, and thus become vulnerable to salinization during storm surges. During hot, dry periods, the fire hazard in peatlands is high (Jayachandran 2009), an example being extensive peat fires in Indonesia exacerbating brown-haze pollution of the whole Asian region in the summer of 2015 (Carmenta, Zabala and Phelps 2015).

The permafrost in boreal peatlands in and around the Arctic Circle is thawing and draining due to climate change, with effects on local and global carbon fluxes (Joosten 2015;

Couture *et al.* 2018). Apart from additional emitted carbon, the permafrost thawing is damaging infrastructure and housing, affecting Arctic people's quality of life. For both tropical and boreal peatlands, the straightforward technical solution to addressing carbon emissions from drained peatlands is to rewet the peatland, bringing the water table back to the soil surface, as is currently being done at a large scale in Indonesia, Canada, Sweden and Switzerland (Zerbe *et al.* 2013).

## 9.6.2 Biodiversity loss

There is evidence of significantly reduced abundance of populations of flora and fauna attributed to wetland loss and pollution impacts, particularly eutrophication, chemical and metal toxicity, and the hazards of plastic and other wastes (WWF 2016). Although wetlands have the capacity to filter and improve water quality, continuous breaking down of organic matter and other nutrients can lead to a tipping point in water quality, beyond which a wetland can no longer regenerate itself, with species assemblages potentially changing markedly.

Fragmentation of rivers through dam building and water diversion, with resultant wetland habitat losses and degradation, has a significant impact on fish populations, especially migratory and endemic fish species. Fish populations are also being overexploited for food. Amphibian species are experiencing dramatic declines through habitat loss, invasive species, disease and pollution, followed by climate change (WWF 2016) (see Figure 9.15). Reptiles and many bird species are deeply affected by loss of wetlands, while aquatic mammals such as otters also suffer local extinctions from habitat loss and overexploitation.

The Living Planet Index (LPI) measures population abundance trends of 881 freshwater species monitored worldwide across

**Figure 9.15: Taxonomic differences in threat frequency for 449 declining freshwater populations in Living Planet Index (LPI) database**

Source: WWF (2016).

**Figure 9.16: Migratory fish from the Living Planet Index (LPI) exhibiting a decline of 41 per cent between 1970 and 2012, with a recent upturn, and freshwater LPI for 881 monitored freshwater species exhibiting an 81 per cent decline**

Source: WWF (2016).

3,324 different populations (see chapter 6). Recent analyses indicate an 81 per cent decline in LPI in freshwater ecosystems between 1970 and 2012, the highest of any habitat type monitored using this index (WWF 2016).

The LPI declined by 41 per cent over this period for migratory fish, based on measurement of over 162 fish species (**Figure 9.16**). Some improvement is evident from 2008 onwards, in response to removing weirs, installing fish ladders, and improving the up- and downstream passage of migratory fish in many places. Migratory species of birds and mammal populations in certain managed wetlands are also starting to recover, in response to habitat conservation and restocking. In contrast, the decline in amphibian and invertebrate wetland species, including insects, is much higher (WWF 2016).

## 9.7 Water infrastructure

### 9.7.1 Drinking water supply: treatment and distribution

Provision of safe, reliable drinking water is a continuing goal of development institutions, requiring modernization of ageing infrastructure and construction of new infrastructure. In many parts of the world, the original infrastructure is deteriorating, requiring upgrading. Provision of drinking water services has not kept pace with the rate of urbanization in many Latin American and Caribbean cities (UNEP 2016f; World Health Organization [WHO] and United Nations Children's Fund [UNICEF] 2016). The Millennium Development Goal (MDG) of halving the number of people without access to safe drinking water by 2015 was achieved by 2010, although progress was uneven across urban and rural populations in all regions (WHO and UNICEF 2015) (**Figure 9.17**).

**Figure 9.17: Variations in trends in drinking water supply coverage across regions**

Source: WHO and UNICEF (2015).

In Asia and the Pacific, progress in provision of drinking water was significant, with 90 per cent of the population having access to improved water supply by 2015. Drinking water supply in Africa increased from 56 per cent in 1990 to 65 per cent in 2013, albeit mostly in urban areas, with 90 per cent of the urban population using improved water sources (UNEP 2016d).

There were significant improvements in access to drinking water in West Asia, with 89 per cent of the population having access to improved water supply by 2015. The reliability and continuity of service remains challenging, however, especially in conflict zones (UNEP 2016c; WHO and UNICEF 2016).

The relatively high quality of North American and Western European drinking water contributes to good public health, with these regions having some of the lowest rates of water-borne disease in the world. Most of the countries in these regions are party to the United Nations Economic Commission for Europe/World Health Organization (WHO) Regional Office for Europe Protocol on Water and Health, and to the 1992 Convention on the Protection and Use of Transboundary Watercourses and International Lakes, a multilateral agreement committing countries to work actively to lower water-borne disease outbreaks (UNEP 2016a; UNEP 2016h).

Gender is a significant factor in water supply, with women and (mostly female) children continuing to carry the major burden and safety risks of acquiring and physically transporting water from source to place of use, particularly in developing countries, despite 1.5 billion more people gaining access to clean water since 2000 (WHO and UNICEF 2017; WHO and UNICEF 2012) (Figure 9.18).

The water collection time burden and the physical labour involved have implications for the livelihoods and safety of women and girls. Time spent by school-age girls collecting water competes with schooling (UNICEF and WHO 2012). It also reduces the ability of women to participate in other

pursuits. It represents a substantial economic drain. Women in India spend an estimated 150 million workdays per year collecting and carrying water, the equivalent of a national income loss of 10 billion rupees (approximately US\$160 million per year). The positive impacts of women being able to spend time on other activities should be widely acknowledged, since economic surveys indicate they typically reinvest up to 90 per cent of their income in their families, improving family health and nutrition, and increasing access to schooling for their children (Unilever *et al.* 2015).

**Figure 9.18: Summary of global progress in providing basic drinking water services and disproportionate impact on women in areas still lacking access to basic drinking water services**

Source: UNICEF and WHO (2012); WHO and UNICEF (2017).

### 9.7.2 Sanitation and wastewater treatment

Improved sanitation, including proper human waste treatment and disposal, is one of the most effective measures for improving public health globally (Sedlak 2014). It remains a challenge, however, in many parts of the world (**Figure 9.19**). Growing megacities, especially in Africa and Asia, do not have adequate sanitation services to accommodate population growth, contributing to open defecation and poor or non-existent wastewater treatment and disposal (UNEP 2016b; UNEP 2016d). Even in areas with improved sanitation, large-scale septic tank and leachfield use in many expanding urban centres affects downstream water supplies as well as groundwater quality.

Approximately 1.4 million people still die annually from treatable diseases associated with pathogen-polluted drinking water and inadequate sanitation, with many millions of others becoming ill (Lozano *et al.* 2013). An estimated 2.3 billion people still lacked access to improved sanitation in 2015. While almost all developed countries had achieved 'universal sanitation coverage' by 2015, only four of the nine developing regions met the sanitation target (Caucasus and Central Asia, East Asia, North Africa, West Asia). The population proportion served by improved sanitation was particularly low in parts of Oceania, sub-Saharan Africa and South Asia (WHO and UNICEF 2015).

There are significant inequalities in access to improved sanitation between rural and urban areas. About 82 per cent of the global urban population has access to improved sanitation, compared with only 51 per cent of the rural global population (WHO and UNICEF 2015). Public sanitary facilities tend to be regulated at local level in most countries. Where facilities are inadequate, they are often especially so for women and girls, including those located in markets, public transport stations and public event venues. Inadequate sanitation in schools has a deleterious effect on education, especially for girls. The problem is compounded for people living in slums and informal settlements lacking access to adequate drinking water and sanitation facilities, or to durable housing, sufficient living area and security of tenure.

### 9.7.3 Dams and reservoirs for water storage and hydroelectric power

Many developing countries continue to construct dams to secure domestic water supply for communities, agricultural irrigation and hydroelectric power generation. Such multifunctional dams can also be operated to provide flood protection to downstream communities, as well as being sensitive to downstream ecological flow requirements (e.g. providing flow pulses to support fish spawning). Hydroelectric power is a key energy source, often critical to provide energy for drinking-water pumps, with additional growth potential evident in Latin America, Africa and Asia (Campuzano *et al.* 2014; UNEP 2016e). In addition, the use of reservoirs for pumped hydro-energy storage systems is increasingly being used to offset the fluctuating nature of other renewable sources of energy (Rehman, Al-Hadhrani and Alam 2015; Barbour *et al.* 2016). On the other hand, efforts to employ run-of-the-river hydroelectric power technologies have shown promise in the Amazon region in supplying electricity to rural communities, exhibiting fewer environmental impacts than traditional dams (Sánchez, Torres and Kalid 2015).

In recent years, dam construction in industrialized countries has slowed considerably. Many older dams are being decommissioned for economic (e.g. high dam operation and maintenance costs) and environmental reasons (e.g. effects on migratory fish, downstream ecosystems and sediment patterns) (O'Connor, Duda and Grant 2015; UNEP 2016e). Dam density nevertheless remains highest in industrialized countries (**Figure 9.20**).

More than 1,270 dams have now been constructed across Africa for irrigation, hydroelectric power production and domestic water supply purposes, although only about 20 per cent of the potential to generate hydroelectric power is currently being utilized and lack of resources to properly maintain dams has resulted in reduced power generating capacity in some places. Increased dam construction in some locations (e.g. Ghana, Benin, Burkina Faso) has caused

**Figure 9.19: Proportion of population using improved sanitation facilities in 2015**

Source: WHO and UNICEF (2015).

**Figure 9.20: Location of dams and reservoirs around the world. Data include dams associated with reservoirs that have a storage capacity of more than 0.1 km<sup>3</sup> and may not represent large dams and reservoirs that have been constructed in more recent years**

Source: Lehner *et al.* (2011).

water contamination, irregular flows, methane emissions and degraded ecosystems, including increased sedimentation, and invasive aquatic plant and animal species (Zarfl *et al.* 2014; UNEP 2016d). Increased sediment trapping associated with reservoirs has been linked to subsidence in deltaic areas and reduced soil fertility, for example the White Volta delta (Boateng, Bray and Hooke 2012; Anthony 2015). Recent construction of large dams has generated significant controversy in many areas, including Africa (e.g. Grand Ethiopian Renaissance Dam; Yihdego, Khalil and Salem 2017), Turkey, the Balkans and the Mekong basin.

Drought is a major risk for hydroelectric power generation. Brazil experienced one of its most debilitating droughts ever in 2015, resulting in decreased reservoir water levels and flows, with many hydroelectric power facilities nearing zero capacity, and causing water shortages to several major Brazilian cities, including São Paulo (Poindexter 2015). The Brazilian example demonstrates the need to foresee conditions that must be dealt with by engineering systems while striving to find an even balance between guaranteeing water supplies and minimizing social or environmental costs.

## 9.8 Impacts

### 9.8.1 Human health

Contamination of water and food by faecal material as a result of poor sanitation and poor hygiene, leading to unsafe drinking water, is a major cause of gastrointestinal illness, particularly diarrhoea. Diseases and organisms associated with diarrhoea include cholera, typhoid, hepatitis A, giardia and cryptosporidium (Lozano *et al.* 2013).

The most important known viral cause of diarrhoea (rotavirus) is being reduced by vaccination programmes (Burnett *et al.* 2017). Open defecation also causes important parasitic diseases transmitted via contact with soil and water (e.g. ascaris, hookworm, water snails) (McCarty, Turkeltaub and Hotez 2014; Lo *et al.* 2017).

© Shutterstock/Couperfield

While hygiene-related diseases have diminished greatly, deaths from diarrhoea still constituted the second most prevalent cause of death (about 13 per cent) in children aged one to four years in 2010 (Lozano *et al.* 2013). Sub-Saharan Africa and South Asia have the highest mortality rates associated with water, sanitation and hygiene (WHO 2017a). Chronic gastrointestinal infections, including those from parasites, cause disability, economic loss and cognitive impairment (Pinkerton *et al.* 2016; Lo *et al.* 2017). Because freshwater provides a habitat for mosquito-breeding, malaria and dengue fever exhibit an even higher disease burden for individuals residing near such habitats, although the situation is slowly improving (e.g. through widespread bed net use) (Ebi *et al.* 2016; Hemingway *et al.* 2016). Recent estimates of the burden of disease due to diarrheal diseases are summarized in **Figure 9.21**.

Health effects from water and sanitation-related diseases appear to vary by gender. Women may have less access to sanitation compared with men and spend more time in environments where open defecation has occurred, thus

incurring a greater risk of parasite exposure. Gendered roles of fetching water and caring for young children, including disposing of their faeces, may further increase the exposure of women to sources of infection. Nevertheless, a recent systematic review and meta-analysis found that, overall, infectious diarrhoea was more common in males. Schistosomiasis was also more common in men, but cholera was more frequent in women (Sevilimedu *et al.* 2016).

Predicted hydrologic cycle changes associated with climate change may exacerbate the environmental health-related diseases, particularly diarrhoea (GBD 2015 DALYs and HALE Collaborators 2016; Mukabutera *et al.* 2016; Musengimana *et al.* 2016; Thiam *et al.* 2017).

### 9.8.2 Food security

Agricultural uses, primarily irrigation, account for 70 per cent of global water withdrawals (FAO 2016). Irrigated land, which accounted for 25 per cent of total cropland in 2012 (FAO 2016),

**Figure 9.21: Morbidity (total disability-adjusted life years, DALYs) from diarrheal diseases (all ages) for females (upper graphic) and males (lower graphic), globally**

Source: GBD 2015 DALYs and HALE Collaborators 2016 (2016).

nevertheless represented half of global crop production (FAO 2016). Climate change effects on temperature and rainfall patterns may drive additional irrigation demands, with water scarcity in many parts possibly limiting crop yields by 2070 (Elliott *et al.* 2014). Efforts are under way worldwide to address predicted hydrologic changes, including shifts to more water-efficient irrigation technologies, while trade of agricultural products provides opportunities for improving food security and adjusting to water scarcity through food imports (United Nations 2017).

The quality and availability of irrigation water and irrigated land are projected to decrease concomitantly, with potential negative effects on food security and human health. About 34.2 million ha of irrigated area has been affected by salinization (Mateo-Sagasta and Burke 2012), representing 10 per cent of total irrigated area globally (324 million ha) (FAO 2017). About 60 per cent of irrigation water does not reach crops due to leakage, spillage and evaporation (FAO 2017), with losses being especially high in developing countries with poor irrigation infrastructure. Improved irrigation efficiency could make a substantial difference. The Mediterranean region could save 35 per cent of its irrigation water through efficiency improvements (Fader *et al.* 2016).

Food security and associated water demands are and will be further stressed by a growing population (FAO 2016). Changing food preferences with rising incomes also increases water demands, with livestock products being more water-intensive than crops. Global meat and dairy consumption are projected to increase by 89 per cent and 81 per cent, respectively, during 2002-2050, with higher growth rates in developing countries (Thornton 2010). However, use of drought-tolerant or flood-tolerant crops will be critical to improving the productivity of the agricultural industry with changing water supply conditions (Zandalinas *et al.* 2018).

The virtual water trade concept (i.e. water embedded in traded products ranging from crops to manufactured goods) illustrates the comparative advantages of certain water uses, including agriculture and energy, in particular regions (Gilmont *et al.* 2018). If water is appropriately priced and allocated, market forces can lead to overall efficiency by capitalizing on these advantages, with virtual water trade redistributing water efficiently, and partially helping to address the disconnect between consumption and production impacts (Mekonnen and Hoekstra 2011; Vörösmarty *et al.* 2015). However, water is not always priced and valued appropriately: water embedded in food commodities is controlled by supply chain corporations and international trade that neither account for ecosystem services nor costs of watershed degradation. The problem lies in the lack of accounting systems for water stewardship in market systems and the practice of subsidies and taxes to keep food prices low (Allan *et al.* 2015; Allan and Matthews 2016). Farmers are faced with the resulting pressures on food prices, further disempowering them from managing and sustaining water and ecosystems (Allan and Matthews 2016).

### 9.8.3 Human safety and security

Degraded water quality, physical and economic water scarcity, and loss of freshwater ecosystem services have significant impacts on human safety and security. Floods and droughts affect ever-larger numbers of vulnerable people (IPCC

2014), with security and migration implications magnified in transboundary basins.

Transboundary cooperation in addressing water scarcity, floods and droughts is challenging, but can enable more effective, efficient management and adaptation by pooling available data, models, scenarios and resources, and enlarging the planning space for locating adaptation measures, including transboundary basins (United Nations Economic Commission for Europe and International Network of Basin Organizations 2015). Transboundary water management creates benefits in international trade, climate change adaptation, economic growth, food security, and improved governance and regional integration.

About 286 international transboundary river basins involving 151 countries pose challenging management problems (UNEP-DHI Partnership and UNEP 2016), as do transboundary lakes and reservoirs. Further, there are currently 366 identified transboundary aquifers and 226 transboundary 'groundwater bodies' underlying almost every nation (International Groundwater Resources Assessment Centre and United Nations Educational Scientific and Cultural Organization - International Hydrological Programme 2015). Even within federated countries (e.g. Australia, India, the United States of America), transboundary problems may be no less acute at a state/provincial level. Although water management has historically led to cooperative, rather than conflicting, outcomes, significant conflicts between stakeholders can still occur over the implementation of international and inter-state agreements. Intensification of water pollution and water scarcity can cause tensions within and between nations, though rarely being the sole trigger of conflict, since a complex mix of social and political conflicts, economic, demographic and environmental factors, and military occupation and water wars (hegemony) is typically the origin of such conflicts.

## 9.9 Policy responses

Human activities now dominate changes in the biosphere and functioning of the Earth system (Green *et al.* 2015; Vörösmarty, Meybeck and Pastore 2015; Vörösmarty *et al.* 2015), "causing complex, and frequently unwanted outcomes including unprecedented changes to global water circulation" (Bhaduri *et al.* 2016).

### Box 9.3: Jordan faces a combined refugee and water crisis

Jordan is one of the world's most water-scarce countries, providing only 150 m<sup>3</sup> of water annually per person, much lower than the 1,000 m<sup>3</sup>/capita level denoting water scarcity. Jordan also currently hosts over 717,000 Syrian and Iraqi refugees, adding to freshwater supply pressures. The formerly permanent lush Azraq Oasis in Jordan used to cover more than 6,000 ha, supporting a variety of plant and animal life, including migratory birds, as well as being the main water source for Jordan's capital city, Amman. However, it was almost completely dried out by 1990, due to overexploitation of the underlying aquifer. By 2017, there were over 35,000 refugees living in the Azraq refugee camp in the oasis (United Nations High Commissioner for Refugees [UNHCR] 2017), an unsustainable situation contributing to further water stress (Alhajahmad and Lockhart 2017).

In addition to many other challenges facing sustainability (Yihdego and Salem 2017), the 'Future We Want' adopted by the Member States of the United Nations in 2012 (Rio +20) recognizes that "water is at the core of sustainable development" (United Nations General Assembly 2012 [66/288]; UNESCO and WWAP 2015). Urgent local-scale actions to meet human water needs, however, may trigger increased regional and global environmental stress, and trade-offs (Bhaduri *et al.* 2016).

With the adoption of the 2030 Agenda for Sustainable Development, the United Nations General Assembly adopted a dedicated water goal (SDG 6), incorporating eight targets, in a holistic framework linking drinking water provision, sanitation, water-use efficiency, water quality and sustainability. The framework includes targets on integrated water resource management and transboundary cooperation, and this section examines a variety of global and regional governance approaches and policy responses to achieve them. The effectiveness of specific examples is explored in Chapter 16.

### 9.9.1 Expanding access to safe drinking water and sanitation (SDG Targets 6.1 and 6.2)

Many policy tools and responses proved successful in increasing access to potable water and improved sanitation during the MDG period (2000-2015). Though water-related investments and appropriate policy tools remain a top global priority, there are significant differences across nations and between rural and urban areas. Innovative technology has played an important role, with the introduction of ventilated improved pit latrines by the United Nations Children's Fund (UNICEF) in the 1980s, and small-bore hand pumps proving effective in many parts of Africa. An array of technologies will be needed to meet the unique circumstances of individual communities and the aggressive goals of SDG targets 6.1 and 6.2. Construction of water-harvesting cisterns in Brazilian rural areas reduced time spent collecting water by 90 per cent (Gomes and Heller 2016). Nonetheless, much still remains to be done to narrow the gaps in access identified in Section 9.7.1.

#### Funding mechanisms

Drinking water and sanitation are recognized as basic human rights with considerable economic benefits realized through investing in water and sanitation provisions. These benefits can be quantified as an overall estimated gain of 1.5 per cent of global gross domestic product (GDP) and a US\$4.3 return for every dollar invested. This is attributable to reduced human health-care costs, greater workplace productivity and involvement through better access to relevant facilities (WHO 2017b).

Inadequate funding, corruption and rapid population growth still limit the achievement of SDG water and sanitation targets in African, Latin American and West Asian countries (UNEP 2016c; UNEP 2016d; UNEP 2016f). The funding gap is partly being addressed with allocation of domestic funds, for example in the 2003 Pan African Implementation and Partnership Conference on Water Declaration (African Union [AU] 2015; UNEP 2016d). Latin American governments have provided wider access to safe potable water for vulnerable populations using public funds (United Nations Economic Commission for Latin America and the Caribbean 2017; UNEP 2016f).

WHO launched 'TrackFin', a methodology to track financing of water, sanitation and hygiene at national level, enabling more evidence-based policymaking (UN-Water and WHO 2015).

#### Market approaches as policy tools

Drinking water access and sanitation are generally considered public goods financed and/or provided through governmental or quasi-governmental entities. However, water pricing for users that reflect water treatment costs (both capital and operations) and incentivize water conservation (Giannakis *et al.* 2016), as well as private investment in water, have become more common in parts of the world, while remaining controversial in others (Harris *et al.* 2015).

#### Regulatory programmes

Regulatory programmes throughout North America, Europe and many parts of Asia rely on enforceable regulations at multiple governmental levels, focusing on delivery of safe drinking water through public utilities and appropriate wastewater treatment before discharging. Drinking-water standards protect public health, especially for vulnerable communities. A robust regulatory programme, focusing on enforceable municipal and specifically industrial discharge permits, could improve the policy approach in many parts of Africa, Asia and Latin America (Masson, Walter and Priester 2013; Aguilar-Barajas *et al.* 2015; UNEP 2016f).

### 9.9.2 Improving water quality (SDG Targets 6.3 and 15.1)

This target focuses on reducing pollution, halving the proportion of untreated wastewater, and increasing water recycling and reuse globally, as a means of improving water quality both for human uses, addressed by the WHO Drinking Water Safety Plan, and aquatic ecosystem health.

In the pan-European region, the basis for wastewater discharge limits, and wastewater collection, discharge and treatment, was set by regional legal instruments, including the 1992 Convention on the Protection and Use of Transboundary Watercourses and International Lakes (which has been open to accession to all United Nations member states since 2016), including its Protocol on Water and Health, and the European Union's Urban Wastewater Treatment Directive (WWAP 2017). The implementation of these at national level has achieved water quality benefits beyond the implementing countries.

Knowledge about the quantity and quality of pollutants, and where they are released into water, remains a prerequisite for addressing water pollution, and its impacts on human and environmental health (Sustainable Facilities Tool 2017). Some countries (or regions) address this goal by Pollutant Release and Transfer Registers (see United Nations Economic Commission for Europe [UNECE] 1998). On a pathway to a circular economy (SDG 12), however, full 'life cycle analysis' and management should be considered.

### 9.9.3 Water-use efficiency and responses to water scarcity (SDG target 6.4)

Addressing water scarcity requires reduction of use and improved water-use efficiency. This includes water reuse, shifts to less demanding crops and industries, water rationing, improved agricultural practices, and use of virtual water trade accounting for embedded water costs. However, even higher

water-use efficiency sometimes does not meet community needs, requiring development of additional water sources (e.g. rainwater harvesting, desalinization, fog interception). Water is transferred across large distances and even between drainage basins in arid regions (e.g. Salem 2009). Management strategies and technological improvements outlined here address water scarcity and stress.

### Water efficiency

Improved water efficiency is central to the water-food-energy nexus, considering factors such as climate change, population and land use (Fader *et al.* 2016). Water efficiency refers to reducing water wastage, in contrast to water conservation, which focuses on reducing water use. To this end, growing food demands require increased productivity per litre of water. Increased water efficiency could also result in reduced water use for energy production, assuming a gradual transition to non-fossil fuel energy sources. Rapid urbanization requires protection of water sources, reduction of reticulation losses and increased water in storage.

Efficiency gains across sectors and regions have been realized through technology and management improvements. As the largest global water user, agriculture represents the greatest potential in water-use efficiency. However, inadequate global data exist to accurately evaluate the overall state and trends of industrial and domestic water-use efficiency. The UN-Water Integrated Monitoring Initiative, initiated in 2014, attempts to address the water-related global monitoring gaps (UN-Water 2017). Existing data are informing the transition from the MDGs to the SDGs, but spatial distribution and frequency of measurements need to improve to strengthen water-resource monitoring, modelling and management.

### Desalinization

Desalinization addresses water scarcity in arid regions and large coastal cities such as the Gaza Strip on the Mediterranean Sea (United Nations Office for the Coordination of Humanitarian Affairs [OCHA] 2017). About 60 per cent of global desalinization occurs in arid West Asian countries

(e.g. Bahrain, Kuwait, Oman, Qatar, Saudi Arabia, United Arab Emirates) (Abuzeid 2014; Abuzeid *et al.* 2014; UNEP 2016c). It is also becoming more common in California, United States of America and eastern Australia, which are prone to recurrent drought years (Little 2015; UNEP 2016a).

Impacts of desalinization include large energy demands, associated greenhouse gas emission risks, the effects of heavy brine releases into coastal ecosystems (Jenkins *et al.* 2012), and entrainment of marine organisms in infrastructure (Dawoud and Al Mulla 2012). The desalinization industry is working to mitigate these impacts and advances in membrane efficiency and energy efficiency may reduce the cost of doing so by 20 per cent over the next five years, and up to 60 per cent over the next 20 years (Voutchkov 2016).

### Water rationing

In water scarcity conditions, water authorities and governments must prioritize water allocations to specific sectors and users. While rationing mechanisms are usually determined by legal water rights, there may also be emergency measures protecting the public and the economy (see also **Box 9.4**).

### Water reuse

Water reuse or reclamation is the concept of treating wastewater as a resource, rather than as variably contaminated waste discharged to the environment (UNESCO and WWAP 2015). Reclaimed water is most commonly used in developed countries for non-potable purposes (e.g. agriculture, landscape and park irrigation), thermal power plant cooling, industrial processes, and enhancing natural or artificial lakes and wetlands (UNEP 2016a; UNEP 2016c). Singapore uses recycled water for indirect potable use and for direct non-potable use. Windhoek (Namibia) uses it to recharge aquifers which thereafter feed water into the bulk water supply. Recycling treated wastewater provides multiple benefits by decreasing water diversions from sensitive ecosystems and reducing wastewater discharges to surface waters, in addition to being a dependable, locally controlled water supply and an opportunity to create green jobs.

#### Box 9.4: How cities face water scarcity

In late February 2018, Cape Town faced the prospect of 'Day Zero', a term coined for the date – then estimated to be 9 July – when the city was expected to run out of water, taps would run dry, and all municipal supply would be rerouted to emergency pickup points (Poplak 2018). This severe urban water scarcity in Cape Town is significant because it could have been the first major modern city to literally run out of municipal water if Day Zero was not averted by sufficient rainfall in the early winter season. There have been past cases of other cities such as Barcelona, regional capital of Catalonia, suffering its worst drought in 2008 since records began 60 years ago, with reservoirs down to a quarter of normal capacity (Keeley 2008). In 2015, Brazil's financial capital, São Paulo, one of the world's most populated cities (over 21.7 million inhabitants) experienced an ordeal similar to that of Cape Town when its main reservoir fell below 4 per cent capacity (Gerberg 2015).

The situation in Cape Town was caused by a three-year drought, considered to be a roughly 1-in-400-year hydrological event, resulting in the levels of the largest storage reservoir (Theewaterskloof Dam) to drop to 11 per cent of capacity (Poplak 2018). However, this proximate cause needs to be understood within a context of efforts to redress historical inequities and overcome institutional divides, and the need to innovate in the face of climate change.

Analysis of water consumption data from 400,000 households (Visser and Brühl 2018) illustrates how Capetonians rallied to avert Day Zero. Over four years of water consumption data indicate that usage by all domestic consumption brackets converged, with 63 per cent of households reaching the recommended target (under 10.5 kilolitres per month) in July 2017, and 30 per cent of households reaching the lower target of 6 kilolitres per household per month even before it came into effect in February 2018. Hence, Cape Town succeeded in halving its water consumption within three years, through a common vision and commitment by its people. A take-home message for Cape Town, and possibly for the world, is that "people's faith in each other's ability to safeguard the remaining water as part of a common pool resource, is critical" (Visser and Brühl 2018).

Using treated wastewater for agricultural irrigation can fertilize crops and benefit production while preventing nutrients and organic matter from entering freshwater systems. Insufficiently treated wastewater, however, can introduce pathogens, metals, excessive nutrients, POPs and emerging contaminants, and pose grave risks to workers and surrounding communities. Increased regulation, investments in treatment and risk assessments are essential for safe wastewater reuse (WHO 2006).

In West Asia, the United Arab Emirates currently reuses all treated wastewaters (290 million m<sup>3</sup> per annum), while Saudi Arabia reuses 166 million m<sup>3</sup>. This reclaimed water is reused for agricultural production in Saudi Arabia's Al Hassa Oasis, after being mixed with groundwater (UNEP 2016c).

Effective management considers an entire watershed or basin as a socio-ecological system integrating across agriculture, forestry, industry, domestic and commercial uses in the ecosystem context. This has improved water availability, sanitation and wastewater treatment in many countries (SDG 6.5 and 6.6) (UNEP 2016a; UNEP 2016f; UNEP 2016h). European river basin management identifies various pressures, classifies monitoring results and enforces environmental objectives (e.g. International Commission for the Protection of the Danube River 2008). There has also been substantial progress in transboundary river basin management (e.g. European Commission 1992; European Commission 2000). Furthering surface and groundwater governance requires cooperation from multinational to local levels, supported by real-time data and information management (Cross *et al.* 2016).

#### 9.9.4 Water governance (SDG Target 6.5)

The commonly accepted definition of integrated water resources management (IWRM) is "a process which promotes the coordinated development and management of water, land and related resources, to maximise economic and social welfare in an equitable manner, without compromising the sustainability of vital ecosystems" (Global Water Partnership 2000). IWRM recognizes water both as a natural resource critical to society and economy and as an integral component of all ecosystems. While discussions over the merits of the IWRM approach continue (e.g. Jeffrey and Gearey 2006; Mukhtarov and Gerlak 2014), it is the major policy concept in place in over one hundred countries (Conca 2006; UNEP 2012a). IWRM is a progressive tool for reform, requiring strong political will for change, and contextual embedding in specific policy problems. However, it is not a panacea for all complexities of water governance (Ingram 2013). The Organisation for Economic Co-operation and Development (OECD) Principles of Water Governance have relevance to IWRM, emphasizing trust between stakeholders. A complementary approach recognizing the buffering capacity of lakes, wetlands and standing water systems is integrated lake basin management (ILBM), which focuses on "gradual, continuous and holistic improvement of basin governance by basin stakeholders" (Research Center for Sustainability and Environment-Shiga University and ILEC 2014).

The SDG 6.5 target calls upon all countries to implement IWRM at all levels by 2030, including through transboundary cooperation. Likely transboundary impacts on water resources are also often addressed in the procedures under the Espoo Convention and its Strategic Environmental Assessment (SEA)

Protocol. To facilitate transboundary water system assessments and management, UN Environment, in collaboration with the Global Environment Facility (GEF) and partners, prepared a global assessment of the status of transboundary lakes, rivers, aquifers and small island groundwater systems, large marine ecosystems and open oceans, Transboundary Waters Assessment Programme (TWAP), (UNEP 2011). The International Groundwater Resources Assessment Centre (IGRAC), a TWAP partner, developed a groundwater information management system to tackle the paucity of standardized quantitative real-time data on key groundwater parameters, and underlined the lack of adequate groundwater governance at all levels.

Recent developments in international water law have significantly strengthened the legal basis regarding shared still (lentic) and flowing (lotic) surface waters and groundwaters. The 1997 Convention on the Law of the Non-navigational Uses of International Watercourses (UN Watercourses Convention) entered into force; the 1992 Convention on the Protection and Use of Transboundary Watercourses and International Lakes (UNECE Water Convention, as amended 2013) was opened to all United Nations member states; and the International Law Commission's 2008 Draft Articles on the Law of Transboundary Aquifers were commended to governments by the United Nations General Assembly. The two conventions, now operating in tandem at the global level, act as an important catalyst for the revision of existing agreements and negotiation of new river, lake and aquifer agreements at basin scale. Financing to support implementation of existing agreements remains a challenge. They are complemented by the United Nations Framework Convention on Climate Change, the Convention on Wetlands of International Importance especially as waterfowl habitat (Ramsar 2016) and the Convention on Biological Diversity (Convention on Biological Diversity [CBD] 1992), which address the protection of water-related ecosystems. Regional-level instruments for water management include the EU Water Framework Directive (European Union 2000).

#### 9.9.5 Surface water-groundwater conjunctive management

Groundwater depletion can lead to streamflow depletion (Hunt 1999; Kendy and Bredehoeft 2006), while streamflow diversions can limit groundwater recharge. Managing these two sources as separate entities arises from limited knowledge of groundwater systems and their spatial and temporal relationships with surface waters, a situation that is no longer justifiable (Famiglietti 2014; McNutt 2014). Current experiences highlight the value of conjunctively managing and using surface and groundwater as 'one water' (Sticklor 2014), thereby buffering against both droughts and floods. Sound management would consider the potential long-term impact of sustained groundwater abstraction on groundwater-dependent ecosystems in arid or semi-arid areas.

Aquifer storage and recovery recharge (Pyne 1995) or managed aquifer recharge (Dillon *et al.* 2009) are becoming important tools to battle chronic water scarcity (e.g. in the state of Arizona, United States of America) (Lacher *et al.* 2014; Scanlon *et al.* 2016; Stefan and Ansems 2017). Underground water storage could play a significant role in semi-arid and arid parts of Africa (e.g. Botswana, South Africa) during episodic heavy rain events, and/or where surface-water storage and transfer options are exhausted (Tredoux, van der Merwe and Peters 2009; Bugar *et al.* 2016). Capture and storage of monsoon

rains in depleted aquifers is being piloted in India (International Water Management Institute 2016).

Water sensitive urban design principles are critical to water-use efficiency, reuse (Wong 2011; Fisher-Jeffes, Carden and Armitage 2017) and flood management (Dai *et al.* 2018); for example, storing reclaimed storm and wastewater from the urban environment in aquifer(s). This approach is especially

effective in mitigating subsidence of, and saline intrusion into, coastal city aquifers (Ortuño *et al.* 2010; Bagan *et al.* 2016).

**Box 9.5** illustrates conjunctive development of surface and groundwater for Hermanus, a coastal town in South Africa, without inducing saline intrusion – a case aimed at mitigation of drought risks by balancing surface- and groundwater storage.

#### Box 9.5: Hermanus, near Cape Town, Western Cape Province, South Africa: A case study for conjunctive surface- and groundwater development and management

Groundwater was used for private housing developments and garden irrigation between 1971 and 2001. The greater Hermanus area water demand was met by the DeBos Dam (blue line, running concurrently with the purple total supply line in **Figure 9.22**). During 2002, 7,750 kilolitres/year of groundwater (green line) came online, with 24,191 kl/year added in 2009, as illustrated by the total supply (purple line) separating from the DeBos Dam inflow (blue line), with the groundwater addition (green line) keeping the supply line above the red demand line.

Groundwater augmentation was particularly effective in keeping supply above demand in 2010, when the DeBos Dam supply (blue line) could not meet it (red line). The water demand was met by surface-water supply from the dam, augmented by three well fields. Water restrictions were introduced in 2009 in anticipation of reduced surface-water supply and later lifted.

In contrast to other towns throughout the Western Cape Province suffering from severe drought, residents in the Greater Hermanus area were only advised on 27 February 2018 that it would be necessary to introduce Level 1B water restrictions from 1 March 2018; although water tariffs would only be increased once the dam had dropped to 40 per cent full level. The DeBos Dam was 46.5 per cent full on this date. (Overstrand Municipality 2018).

Figure 9.22: Hermanus Conjunctive Use

Source: Overstrand Municipality 2018.

Figure 9.23: Supply of and demand for water, Greater Hermanus, 1971-2001 (a) and 2002-2017 (b)

Source: Overstrand Municipality (2018).

Underlying successful conjunctive use is comprehensive monitoring, modelling and risk assessment of the aquifer and surface-water source(s), associated catchment areas and social systems in a learn-by-doing approach (Bidwell 2003). Managing aquifer resources requires a land-use zoning system based on aquifer vulnerability and constraints, to enable adequate abstraction rates and natural recharge (Cross *et al.* 2016).

Monitoring and management of the full water-use cycle by the private sector (e.g. agriculture and mining) is gaining recognition. Examples of stewardship programmes include Woolworths in South Africa (in partnership with WWF-South Africa, WWF-UK, the Alliance for Water Stewardship and Marks and Spencer); Coca-Cola and the United States Agency for International Development (USAID) Water and Development Alliance, H&M and WaterAid (Workers' Need Project in India), Unilever and Nestlé in Europe. The CEO Water Mandate (<https://ceowatermandate.org>) was instrumental in promoting the business benefits of water stewardship. This intersection between water governance, use, users, real-time monitoring, and modelling to inform evidence-based resource development and management is gaining momentum. In the fast-growing city of Bangalore, where 40 per cent of the water entering the system is lost to leakages, Water Supply and Sewerage Works formed an alliance with IBM and installed flow meters at several critical points in the water reticulation system. Data is being transmitted via GSM (Global System for Mobile communications) technology to a central Supervisory Control and Data Acquisition (SCADA) server to be transformed, aggregated and presented on a web interface and mobile application for end users.

#### 9.9.6 Protecting and restoring water ecosystems (SDG target 6.6)

The importance of water-related ecosystems is specifically reflected in the water goal (SDG 6) and the terrestrial

biodiversity goal (SDG 15). Target 6.6 aims "to protect and restore water-related ecosystems, including mountains, forests, wetlands, rivers, aquifers and lakes," emphasizing their crucial role in water cycle functions and watershed management.

SDG 6.6 monitors changes in the spatial extent of water-related ecosystems. Given wetland losses and associated biodiversity declines, many countries respond with natural wetland protection and management programmes and environmental flow requirements (e.g. Mexico's water reserves; South African National Water Act 1998 [Government of South Africa 1998]). River and wetland restoration and construction efforts are proceeding, including constructed wetlands for storm water treatment in Australia, recapturing floodplain areas in The Netherlands, and reconnecting wetlands and lakes to the main stem of the Yangtze River in China. Improved Earth observation data, combined with a classification methodology, enable countries to gain accurate pictures of their water-related ecosystems. However, there is a pressing need to extend on-the-ground monitoring of water cycle components and harmonize observations.

The Ramsar Convention on Wetlands (1971) is a multinational environmental agreement, devoted specifically to the conservation and wise use of wetlands. Each signatory country must designate and protect one or more "Wetlands of International Importance" (known as 'Ramsar sites'). As Contracting Parties to the Convention, 170 countries had designated 2,326 Ramsar sites by early 2018. The total wetland area protected by the Ramsar designation has increased from 81 million ha to almost 250 million ha since 2000 (Figure 9.24). New Ramsar sites designated in recent years tend to follow hydrological boundaries, to protect whole catchments and river basins (Ramsar 2018).

Figure 9.24: Ramsar sites designated by year and by region

## 9.10 Conclusions

Widespread water scarcity is now an outcome of the connections and linkages between the hydrological cycle, unsustainable agriculture, and energy systems. At a local level, water is contested and plays a part in social conflicts and human migration decisions, against this backdrop of complex interlinkages. At a global level, the water cycle integrates the impacts of human activities, population growth and climate change. The deterioration of water quality across regions and continents threatens the health of people and ecosystems, while climate change is accelerating the water cycle and causing increased impacts on communities through storms,

floods and droughts, extreme wildfires and landslides, as well as increasing dust and sandstorms in the most arid areas. Hence water, in addition to being a public good, is now becoming a risk multiplier for the health of people and of the planet.

However, the realization of SDG 6 (water) targets can be achieved through engaging public, private and non-governmental sectors, civil society and local actors, and by mutual reinforcement or trade-offs that also consider other interlinked SDG goals focused on poverty eradication (SDG 1), food security (SDG 2), health (SDG 3), gender equity (SDG 5), sustainable cities (SDG 11) and protection of biodiversity (SDGs 14 and 15).

Multinational environmental agreements (MEAs) governing water resources and water-related ecosystem management and climate change can support the embedding of integrated water resources management in the rules of law – through national and local legislation.

Effective, efficient and transparent water resources governance is required that includes improved collaboration and

coordination between governments, technical institutions, non-governmental organizations and civil society towards improved monitoring and data quality, culminating in better hydrological and hydrogeological services, as discussed in the recent WMO conference held in May 2018 (World Meteorological Organization 2018). Increased investment in the scope and rigor of standardized water data is essential to improve policy and governance for sound water management.

## 10.1 The Context

Policies are crucial in determining and improving the state of our environment. A simple way to think about policy and policy instruments is that a policy is a statement of intent to change behaviour in a positive way, while an instrument is the means or a specific measure to translate that intent into action (Mees *et al.* 2014). Therefore, discussion of effectiveness of environmental policies means addressing both aspects. Goal setting (including targets, indicators and time frames) is an important step towards legitimization of environmental policies. Execution of the policy instruments is through effective governance. Governance is “the process whereby societies or organizations make important decisions, determine whom they involve and how they render account” (United Nations Economic and Social Council 2006). The recently adopted Sustainable Development Goals (SDGs) give a new impetus to ‘governing through goals’ (Yoshida and Zusman 2015).

Strong environmental policies form an integral component of UN Environment’s theory of change, which posits alternative pathways to global sustainable development. UN Environment defines a theory of change as when “an intervention depicts the causal pathways from outputs through outcomes via intermediate states towards impact” (United Nations Environment Programme [UNEP] 2017). The theory of change further defines the external factors that influence change along the major pathways – that is factors that affect whether one result can lead to the next. These contributing factors are called drivers and assumptions.

The theory of change for the fifth Global Environment Outlook (GEO-5) showed an expectation that GEO should be policy relevant and draw from a good understanding of global and regional policy issues (UNEP 2012). In GEO-6, however, policy effectiveness is seen to be more central in the theory of change, as shown in Annex 1-3. Reflecting on the mandate of UN Environment’s High Level Intergovernmental and Stakeholder Advisory Group, it is no longer sufficient to be merely policy relevant. Member governments want to know which policies are most effective in dealing with seemingly intransigent and insurmountable environmental problems. Using the Drivers, Pressures, State, Impact, Response (DPSIR) framework (see Figure 1.2, Chapter 1), current responses to environmental problems are discussed in the thematic chapters in Part A of this report, while Part B addresses the question of when these policies are effective, and Part C incorporates the most promising policy approaches into the pathways of transformation. While GEO-6 is not policy prescriptive, it offers guidance to governments and policymakers who would like to know which policies have worked best in which circumstances, under what governance arrangements and whether that experience is transferable to other contexts.

## 10.2 Environmental policy and governance

Environmental policies are pursued through a multitude of modes of governance and are designed to promote desirable behaviours by a defined set of actors and to overcome a range of challenges that impede effective environmental

management. Policy objectives are to be achieved via policy measures or instruments – structured activities targeted at changing other activities in society towards achieving environmental goals. Not all effective policy instruments are for environmental policy alone, other instruments (e.g. in energy and transport policy) may include environmental policy goals, often as secondary goals to the prime non-environmental goal (e.g. reducing congestion). This is the usual case now in most integrated policies (as discussed in Chapter 11). Accordingly, environmental governance extends well beyond environmental ministries.

Governments are often thought of as the primary domain for development and implementation of policies. While governments are often the most important actors in formulating, implementing and enforcing policy instruments, they do not act alone, and various governance arrangements are needed. Effective policies usually involve a wide range of stakeholder inputs throughout the policy cycle. Governments at all levels are active in policy formulation and implementation, as are private sector and civil society actors. Roles and responsibilities are spread not only between governmental and non-governmental institutions, but also across all levels of governance.

Politicians, policy think tanks, education and research institutions, non-governmental organizations (NGOs), civil society organizations (CSOs), lobbyists, communities and companies all have roles to play in influencing policy outcomes in different contexts. At the regional and global levels, policy instruments are created and implemented by global, regional or national institutions in multilayered governance arrangements. There is also a growing number of ‘public-private partnerships’ and ‘corporate sustainability initiatives’, including the emergence of ‘business-NGO interactions’ aimed at stimulating responsible and sustainable behaviour in specific sectors (Forsyth 2005; van Tulder *et al.* 2016). Such partnerships (e.g. UN Environment’s Clean Seas Initiative) emerged in the design and production of goods, risk assessments, due diligence, training, monitoring, reporting and mediation, transparency in supply chains and more. In many countries, citizens and communities are also contributing to the realization of collective environmental goals. These are often framed as ‘citizen co-production’ and/or ‘community-based initiatives’ (Mees, Crabbé and Driessen 2017).

The challenge is for all these actors, layers and levels to mesh together and provide a coherent mix of policies appropriate for the scale and period of application and consistent with the national social, cultural, historical and political context (European Environment Agency [EEA] 2001a; EEA 2001b; European Commission [EC] 2012; Niles and Lubell 2012; EEA 2017).

Polycentric governance is a source of innovation and by enabling the competition of ideas, collaboration and alignment, it creates momentum for environmental policies (Jordan and Huitema 2014). However, dispersion of responsibility may lead to fragmented policies, poorly defined roles and responsibilities, weak follow-up and monitoring mechanisms, lack of accountability for results or a stalemate in decision-making.

### 10.3 Policy instruments

Policy instruments come in multiple forms and can be implemented by multiple actors (not only governments) at multiple levels of governance (Mees *et al.* 2014; Keskitalo *et al.* 2016). Policy instruments can be aimed at various mechanisms:

- i. available alternatives can be amended;
- ii. impacts of alternatives can be changed; and
- iii. evaluation of outcomes can be influenced (Boersema and Reijnders eds. 2009).

These forms vary between traditional top-down steering by governments to self-regulation of business organizations. Some forms are more, and others less, successful in fulfilling their policy objectives. It is often stated that collaborative modes of governance, which rely on stakeholder participation, are needed to address the complex, multi-scalar and cross-sectoral dimensions of environmental problems (Challies *et al.* 2017; Kochskämper *et al.* eds. 2018). Moreover, increasing understanding of environmental challenges have changed policy approaches and instruments from targeted policies and single-use instruments to policy integration and raising of public awareness to policy coherence and systematic approaches (e.g. green economy) (EEA 2017).

One policy tool to address transboundary environmental problems and maintain 'the commons' is robust and legally binding international agreements. However, given the structure and legal basis of international law-making, such agreements often fall short in meeting the ambitions of the front-running or most affected countries (Sandler 2017). Therefore, coalitions or clubs of countries may step in and develop more ambitious environmental policies (Hovi *et al.* 2016).

An often-stated understanding of environmental policy instruments is that they can be 'carrots, sticks or sermons,' although this is only a partial characterization of the full range (Niles and Lubell 2012). Some common types of policy instrument include legislation and regulatory policies, financial incentives/disincentives, voluntary approaches, treaties and agreements, and international soft law (Hildén, Jordan and Rayner 2014). GEO-4 used the following traditional structure: regulations and standards, market-based instruments, voluntary agreements, research and development, and information instruments (UNEP 2007). In GEO-5, common threads were traced between and across different world regions, emphasizing particular policy approaches that had proven successful in a number of cases. Successful policy responses in several regions were assumed to be more likely to accelerate achievement of internationally agreed goals. Within the DPSIR framework, policies that address 'drivers' tend to be preferred, as they intend to address the roots of environmental problems rather than treating the symptoms (UNEP 2012). For GEO-6, the typology in Table 10.1 has been used to provide guidance on the selection of types of policies instruments and governance approaches and associated case studies. Note, however, that the typology is not intended to be an exhaustive coverage of all possible environmental policies or policy instruments.

Environmental policies ultimately aim to preserve a state of the environment that protects habitats, safeguards

ecosystem services and minimizes risks for human health from pollution. Therefore, environmental policies have been typically developed to protect different environmental media (air, water, land), to influence the state of the environment outlined in Part A of this report, and usually under the control of an environment ministry. However, effective environmental policies not only address the state of the environment, but also the drivers and pressures originating from social and economic activities (outlined in Chapter 2). Accordingly, governments across the world have developed institutions and policies that address the most important polluting sectors, such as energy, mobility, industry and agriculture (Organisation for Economic Co-operation and Development [OECD] 2016).

In Part B of this report, a selection of the most commonly adopted policies, cutting-edge policies and policy clusters that show real promise in each thematic area and cross-cutting issues are analysed, recognizing that there are literally thousands of policies and policy instruments and it is not possible to cover them all. The selected policies represent a sample from different types of policy instruments and governance approaches (see **Table 10.1**) from different regions of the world.

### 10.4 Policy mixes and coherence

Given the multiple actors and factors causing environmental deterioration and the various types of barriers to environmental innovation, a single policy instrument is rather unlikely to be sufficient for achieving the desired goals. Against this background and the multiple challenges to address when developing effective environmental policies, adopting policy mixes rather than a single policy is claimed to be more effective (Jänicke *et al.* 2000; Mees *et al.* 2014; Kivimaa and Kern 2016).

However, different policies may not always complement each other, but could impair each other (e.g. economic incentives may undercut intrinsic motivation). A policy package, portfolio, mix or cluster is a collection of policy instruments all designed to achieve a common goal or set of intentions (Lay *et al.* 2017). When developing policy mixes, their coherence has to be ensured in order to achieve optimal results (Howlett and Rayner 2007; Huttunen, Kivimaa and Virkamäki 2014).

Policy coherence is the systematic promotion of mutually reinforcing policies that can accumulate synergies in attempting to achieve agreed objectives (OECD 2016). Policy coherence can be sectoral, transnational, across governance regimes, multi-level (from global to local) and/or from policy objective through to instrument design and implementation practice (Hood 2011). Policy coherence occurs when the balance of policies is aligned with that common goal or set of intentions.

In addition to policy coherence, policy synergy is also necessary. In order to realize environmental objectives, environmental concerns need to be incorporated in other policy sectors. This is often referred to as policy synergy or environmental policy integration and contributes to policy coherence (Hood 2011; Lay *et al.* 2017). Policy synergy occurs when successive policy instruments have a cumulative or reinforcing impact in achieving the common goal or overarching policy aspiration (OECD *et al.* 2015).

Table 10.1: Policy typology

| Policy instrument / governance approach          | Point of intervention <sup>a</sup>                                                               | Assumed causal mechanism                                                                                                                                                                                                                                                                                                                                                                  | Barriers to effectiveness                                                                            | Potential costs                                                                                                 | Typical policy instruments                                                                                                                    | Contextual requirements                                                   |
|--------------------------------------------------|--------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------|
| Command and Control                              | Industrial processes and products<br>Technologies<br>End of pipe or smokestack pollution control | Prohibition of environmentally harmful technologies (products and processes) or demanding environmentally friendly technologies as part of permitting => reduced emissions/resource use => if emissions/resource use cannot be reduced enough by upstream controls, then improved waste management is needed. Can also address enabling issues such as property rights and access issues. | Lack of monitoring<br>Corruption.                                                                    | Costs for firms, harmful for competitiveness.<br>No incentives to innovate.                                     | Permitting processes/ fines.<br>Discharge/emission standards.<br>Total pollutant load caps<br>Real-time monitoring systems.<br>Legal reviews. | Administrative capacities.<br>Self-reporting by industry.                 |
| Promotion of innovation                          | Green innovation                                                                                 | Incentivizing R&D in green technologies => introducing green technologies to markets (=> cost savings + exports)                                                                                                                                                                                                                                                                          | Spill over.                                                                                          | Additional costs.                                                                                               | Subsidies, tax relief for R&D, green procurement.                                                                                             | Public and private budgets.                                               |
| Market-based/ economic incentives                | Pricing of products or processes                                                                 | Change of relative prices between environmentally harmful and green technologies<br>=> increased markets for green services;<br>=> incentives to innovate and disincentives to cause environmental harm.                                                                                                                                                                                  | Lack of significance within the overall context of consumer budgets and/or industrial capital plans. | Distributional/ regressive impacts, harmful for competitiveness.<br>Retrofitting costs for existing industries. | Cap and trade, public procurement, removal of subsidies.                                                                                      | Private investment in new products or processes<br>Effective tax regimes. |
| Convincing consumers, employees and stockholders | Public information, education, knowledge, awareness, advocacy                                    | Knowledgeable consumers and producers will voluntarily choose environmentally sound products and processes.                                                                                                                                                                                                                                                                               | Cost disincentives<br>Inadequate supply of alternative products and processes.                       | Power imbalances cause poor choices by consumers.                                                               | Campaigning.<br>Labelling.<br>Certifying.<br>Nudging.<br>Stockholder voting blocs.                                                            | Media and stock markets<br>Education system.                              |

<sup>a</sup> Point of intervention refers to the issues considered as key for environmental degradation, especially its improvement (e.g. technologies, innovation, infrastructures, actors, behaviour).  
EIA: Environmental Impact Assessment; IA: Impact Assessment; R&D: research and development; SEA: Strategic Environmental Assessment.

Policy conflict, on the other hand, sees the impact of one set of policies, often in unrelated sectors or from an external actor, undermining the intended outcomes of the desired environmental policies. For example, providing a subsidy to first car buyers may conflict with policies to reduce air pollution from transportation. Accordingly, any analysis of environmental policy effectiveness also needs to address the influence of economic and social policies in other domains (Perrels 2001; Interwies, Görrlach and Newcombe 2007; Lambin *et al.* 2014).

## 10.5 Methodology adopted to assess policy effectiveness

The assessment of policy effectiveness in the remaining chapters of Part B serves three main purposes:

1. To showcase policies and governance approaches at all levels that have demonstrated an impact and that can potentially be applied elsewhere.
2. To identify needs for further action by improving the effectiveness of policies. The analysis builds as much as possible on quantification of policy effectiveness (i.e. indication of how much/how often policies do have an effect, not only how and why).
3. To establish methods and best available knowledge for assessing policy effectiveness that can be used beyond GEO-6 for improving the evidence base of policymaking and thereby strengthen environmental policies.

The gold standard to evaluate and quantify the effectiveness of policies is the comparison of empirical observations with a control group in an experimental design or with a counterfactual scenario. However, constructing such

experiments or scenarios is in many cases costly if not impossible as the objects of policy interventions are complex social systems. For example, it is not possible to predict the reactions of markets with or without policy interventions. Furthermore, in many cases control groups cannot be identified and it may be unethical to deliberately withhold the benefits of a policy.

Evaluating policy effectiveness is still possible based on theoretical assumptions and empirical observations of policy impact. Theory-based evaluation uses an explicit theory of change throughout the causal chain from policy outputs to outcomes and final impacts (Blamey and Mackenzie 2007; Rogers and Weiss 2007).

Attributing causality to policies in often extensive and complex causal chains from policy, through its implementation, to behavioural changes and processes that are triggered, to impacts, indirect and induced impacts, is a particular challenge for policy evaluation (Forss, Marra and Schwartz eds. 2011). A conceptual approach was adopted in Part B of this report which aims to minimize the problem of attribution by combining a top-down and a bottom-up perspective (Sabatier 1986). The top-down perspective shown in **Figure 10.1** starts with the policy and traces the causal chains that are expected from the implementation of the policy. The bottom-up perspective starts from the observed outcomes and uses policy-relevant indicators to trace the causalities back to the policy interventions. This helps analysts to evaluate the effects of policy mixes. Both perspectives have their shortcomings – the top-down perspective tends to overemphasize the impacts of policies compared to other factors, the bottom-up perspective tends to overemphasize the impacts of contextual factors.

**Figure 10.1: Methodological approach for assessing policy effectiveness: top-down and bottom-up approach**

DPSIR: Drivers, Pressures, State, Impact, Response.

The conceptual approach taken in relation to policy effectiveness in this section follows this dual perspective, combining a theory-based top-down evaluation and a bottom-up, observed outcomes-based evaluation. Despite the recognized shortcomings, this dual approach is the best available option for assessing policy effectiveness.

The top-down approach is particularly suitable for identifying policies that may serve as examples of good practice that can be applied elsewhere (the primary goal of such evaluations). Chapters 12-17 provide a narrative description of the most commonly implemented or most important policy instruments in the five thematic areas, as well as the cross-cutting policies that have positive or negative impacts on the themes. In addition, they have identified policy instruments at the cutting edge that appear to have considerable potential but have not been widely adopted to date, through a series of case studies, evaluated against the criteria listed in Section 10.6. However, a quantification of aggregate effects of this mix of policies will not be possible due to a lack of representative sampling and the limited number of policies reviewed.

The bottom-up evaluation, based on policy-relevant indicators, complements the analysis and contributes in particular to the quantification and the identification of needs for further action (goal 2 of the evaluation). The methods for each approach are further elaborated in the following sections. Figure 10.1 graphically summarizes how to assess policy effectiveness through these top-down and bottom-up evaluations.

## 10.6 Top-down evaluation methodology

The top-down evaluation of policy effectiveness in GEO-6 starts with the selection of policies and governance arrangements and associated cases. For each thematic area, up to five promising policy types or governance arrangements are selected by considering the coverage of the variety of policy types and governance arrangements, geographical diversity and the availability of data.

These policy types and governance arrangements are then evaluated using the available knowledge based on peer-reviewed publications, official reports and statistics.

Next, for each policy type or governance arrangement selected and evaluated, a case exemplifying the implementation of the policy is chosen and assessed in terms of policy effectiveness according to a common research protocol covering the achievement of stated objectives or improvement of relevant indicators, the quality criteria of policy formulation and implementation (e.g. level of participation), *ex ante* or *ex post* assessments and the contextual requirements for the effectiveness.

Note that 'policy effectiveness' is not merely a matter of achieving the policy goals at any cost. For example, an island nation may decide on a policy of carbon neutrality and attempt to achieve it by banning import of gasoline and fuel oil. If the local fishers are unable, however, to power their boats then there could be widespread malnutrition as fish

disappears from the diet. Crime might also increase in order to meet the unsatisfied demand for fuel.

The criteria for assessing the cases are derived from the literature on policy design and effectiveness. They are not prescriptive in terms of methods, data, policy instruments or causal chains, but on each aspect the relevant knowledge from the literature is presented. As all case studies are based on secondary data analysis, the research protocol necessarily leaves discretion to be adapted. For example, evaluation studies may be based on measuring effectiveness against the stated goal of policymakers, against an indicator, against a control group or against a counterfactual scenario. The research protocol does not prescribe one or the other method for assessment, but provides transparency on the underlying methods, theories and data sources of the individual case study.

The evaluation criteria and associated guiding questions for the case studies are the following:

1. Effectiveness/goal achievement – What effects did the policy have on the targeted problem?
2. Unintended effects – What were the unintended effects of this policy?
3. Baseline – Was the baseline defined at the policy design stage?
4. Coherence/convergence/synergy – How does the policy intersect with other related policies?
5. Co-benefits – Did the policy design provide for co-benefits?
6. Equity/winners and losers – What are the effects of this policy on different population groups?
7. Enabling/constraining factors – What external factors are likely to influence the intended policy effects?
8. Cost/cost-effectiveness – What were the financial/economic costs and benefits of this policy? Is it the most cost-effective or the least-cost approach?
9. Time frame – Was the policy implemented within the expected time frame?
10. Feasibility/implementability – Is the policy technically feasible in the institutional context?
11. Acceptability – Do the relevant policy stakeholders view the policy as generally acceptable?
12. Stakeholder involvement – To what extent were affected stakeholders actively involved in implementation?
13. Any other factors – such as transformative potential, intergenerational effects, transboundary impacts, sociocultural concerns, political interference, enforcement issues, compliance with legal standards (e.g. national/international human rights).

As a caveat, there is abundant evidence from the environmental policy and governance literature that policy effectiveness is highly context dependent (Jordan and Huitema 2014). Therefore, effective policies from one region or country cannot simply be transferred to another context. Social, cultural, historical and political differences do matter.

This top-down evaluation is complemented by a bottom-up evaluation described in the next section.

## 10.7 Bottom-up evaluation methodology

An indicator-based assessment of policy-sensitive/policy-relevant indicators for each thematic area and cross-cutting issue complements the top-down evaluation and provides evidence on the quantification of policy effectiveness (Hezri and Dovers 2006; Bauler 2012; Moldan, Janoušková and Hák 2012). Indicators are constructed to measure the state of complex systems which may not be observed directly or comprehensively. They measure certain aspects and based on theoretical considerations and/or evidence, conclusions can be drawn regarding the state of the overall system. For the purpose of measuring policy effectiveness, it is necessary to be explicit on the theory regarding how policies and the selected indicator interact.

Indicators that provide insights to the state of ecological or economic systems and their environmental performance are in many cases not directly influenced by policies. Instead, cultural, structural, political, geographical and other factors may intervene. Measuring the policy outputs (e.g. adoption of policy instruments) would not adequately capture the preferences of different countries for one or another instrument. For example, for mitigating greenhouse gas (GHG) emissions, one country may regulate emissions, another imposes taxes or emission trading schemes, a third implements information campaigns or subsidizes climate-friendly technologies. In each of these cases, the expected impact will be reducing emissions of GHGs. The indicator is influenced, however, by the industrial structure, natural conditions, level of income and other factors that are not, or not directly, impacted by (environmental) policies.

Therefore, an indicator-based assessment must have a transparent underlying theory on how policies would impact on the selected indicator and what other factors may also have an influence. **Figure 10.2** shows the underlying rationale for developing the theory on the relationship between policies and relevant indicators.

**Figure 10.2: Approach of assessing policy effectiveness from the bottom-up**

SoE: State of Environment

The analysis of data for the selected indicators has multiple objectives:

- ❖ To analyse progress on achieving internationally agreed goals since GEO-5 (including the SDGs);
- ❖ To identify countries or groups of countries that demonstrate – with their policy approaches and implementation experience – a high level of effectiveness; and
- ❖ To quantify policy impacts and thus identify where further action may be needed.

The selection of indicators is based on the following rationale:

- ❖ There is a causal relationship determining the variation of the indicator to policy instrument (preferably, different types of policy instruments) and their implementation can be demonstrated;
- ❖ The indicator has a relationship to a multilateral environmental agreement (MEA) and/or SDGs to guarantee the alignment of the analysis with the future global agenda;
- ❖ Data need to be available (at least at country level, and possibly at global scale, and also in a time series);
- ❖ The indicator should be relevant for the thematic area, i.e. it would provide insights into the state of the environment for the respective thematic area; the indicator should ideally consider the policy responses discussed in Part A of this report.

For each indicator, the following aspects are considered, based on peer-reviewed literature.

1. Scope and measurement: the indicator should provide insight into the state of the environment for the respective thematic area. The argument behind selecting each indicator in a thematic area is made transparent.
2. Policy relevance: the causal relationship between policy measures and instruments and the indicator is specified. Not all indicators are policy sensitive but the following questions can be asked of the indicators. Through which mechanisms would policies impact on the indicator? What triggers (e.g. prices, command and control, persuasion) are used by policy instruments that would impact on the respective indicator? Which actors change their behaviour as a result of these policies and how does this impact on the indicator? How does this indicator relate to the state of the environment (ideally at the country level)? What processes are triggered by changes in the indicator and what are the impacts on the environment?
3. Causal relations/causal chain(s): policy-sensitive indicators are those for which a causal relationship to policies and their implementation can be demonstrated. While attribution of causality is challenging, indicators can be selected for their responsiveness to policies as compared to other intervening factors such as sociodemographic factors, infrastructures, natural conditions and culture. Is there any evidence showing that indicators can be associated with these causal output-outcome-impact chains? 'Outputs' and 'outcomes' are processes that are triggered by the policy and 'impacts' are the ultimate effects of a policy. Initial impact may again trigger other processes and have indirect or secondary impacts as well.

4. The analysis must consider other factors impacting on the indicator.  
Is there any evidence showing that other factors not directly or immediately affected by policies (natural conditions, infrastructure, cultural, natural disasters) have demonstrated any impact on the indicator? Are there uncertainties on causal relationships that affect the indicator?
5. Graphic representation and visualization: for each indicator, data are presented on progress towards achieving the relevant international goals as well as the development of each indicator at the country level (cross-longitudinal and cross-sectional analysis).  
Are there outstanding countries in terms of best performer or poor performer? Based on the previous steps a critical reflection should be undertaken: Is it possible to attribute this to policies and other factors? What are the uncertainties?
6. Possible alternative indicators: in case there are suggestions in the literature for other indicators to measure policy effectiveness for the given thematic area, these are discussed.  
Is the suitability or relevance of the indicator disputed? Are there other, alternative indicators proposed to measure

policy effectiveness? Why were these not considered in the analysis?

The indicator-based assessment of policy-sensitive indicators described above does not aim for comprehensiveness: it is certainly not possible to cover all indicators and all aspects for all the thematic areas and cross-cutting issues. This very partial coverage is acknowledged, and further efforts are needed in future GEOs to improve the coverage.

## 10.8 Content of Part B

The remainder of Part B reflects these top-down and bottom-up approaches, with Chapter 11, based on literature, focusing on issues of policy design, spatial and temporal policy diffusion and evolution, and the effectiveness of international and multi-level governance. Chapters 12-17 cover the key policy approaches mentioned in Part A of the report, under the 'responses' section of the DPSIR framework. For each of these key policy approaches, a case study is used to exemplify the application of the policy approach in a specific context. Policy-sensitive indicators for each thematic area and cross-cutting issue are also included in these six chapters. Chapter 18 draws conclusions and key messages for Part B and provides guidance for policymakers and the link to Part C of the report.

# Chapter 11

## Policy Theory and Practice

**Coordinating Lead Authors:** Klaus Jacob (Freie universität Berlin), Peter King (Institute for Global Environmental Strategies)

**Lead Authors:** Pedro Fidelman (Centre for Policy Futures, University of Queensland), Leandra Regina Gonçalves (University of Campinas/Centre for Environmental Studies and Research [NEPAM]), James Hollway (Graduate Institute of International and Development Studies), Sebastian Sewerin (Swiss Federal Institute of Technology Zurich [ETH Zurich])

**Fellow:** He Chenmin (Peking University)

# Executive summary

**Environmental policy struggles with some conceptual and empirical challenges, so a good starting point for analysis is what constitutes ‘good’ policy design.** Within the definition of ‘good’ policy design, ecosystem properties and problems, the performance of existing policies, practices and actors need to be considered common elements. Analysts and policymakers should better understand the temporal dynamics of policy change, how and why specific policies work (or not) and how policy choices interact in increasingly complex policy mixes. {11.2}

**In the field of environmental policy research, diffusion across borders has featured prominently, especially in relation to renewable energy policies such as feed-in tariffs, renewable portfolio standards and emissions trading.** Among four possible mechanisms of renewable energy policy diffusion (emulation, suasion, learning and competition), suasion and emulation were found to be more common than learning and competition. There has been little research on post-adoption dynamics of diffused policies, with a risk of undermining other sector policies and policy coherence. {11.2.1}

**In relation to how policies change over time and what factors drive these changes, two approaches are dominant in the literature:** policy stability—or lock-in—on the one hand and punctuated equilibrium on the other. Punctuations may be driven by external shocks that rock the otherwise stable policy environment until a new equilibrium is established. Such punctuations may open opportunities for new environmental policies (e.g. the impact of Japan’s Fukushima nuclear disaster on Germany’s policy decision to phase out nuclear power). Often, to avoid risks from taking decisions with unwanted side effects, policymakers tend to delay decisive action as long as possible and, confronted with external shocks, choose symbolic action rather than effective policymaking. {11.2.2}

**Policy innovation can be regarded as a mix of invention (new or novel approaches), diffusion (transfer and adoption) and monitoring of effects (outcomes, impacts and possibly disruption).** Good practice suggests that multiple innovative policies should be implemented as a form of quasi-experiment, with best practices emerging from the monitored effects. {11.2.2}

**Evaluation of policy effectiveness often comes down to expert judgement, as there is no commonly agreed approach to assessing effectiveness.** Ideally, a combination of quantitative and qualitative assessments will be most reliable in assessing policy effectiveness. Some policy design tools that can supplement expert judgement are: (i) cost–benefit analysis and cost-effectiveness analysis, both of which can be used *ex ante* (before implementation) or *ex post* (after implementation); (ii) regulatory impact analysis; (iii) benchmarking or distance to goal or target; and (iv) content analysis or pattern matching. {11.2.3}

**A key lesson learned is to carefully craft a mix of policies that are well aligned with an overall policy objective followed by monitoring of the actual effects to determine best practice and likely contributions of different policies.**

For example, climate change mitigation policy objectives will need a comprehensive mix of carbon pricing, support for energy efficiency and renewable energy, phasing out fossil fuel subsidies, innovation policies, preventing lock-in of certain technologies and changes in consumer behaviour, among others. {11.2.4}

**Environmental objectives cannot be realized by environmental policies alone, but need to be incorporated in non-environmental policy sectors too.** Environmental ambitions often clash with other sectoral goals, so environmental policy integration should be used to address conflicts between environmental and other policy objectives. A corollary to policy integration is policy coherence: the promotion of mutually reinforcing policy actions creating synergies towards achieving objectives in multiple sectors. {11.3}

**An important argument in favour of environmental policy integration is the economic and social co-benefits that can be expected or demonstrated from implementing environmental policies.** These may include additional economic growth from innovation, savings from more efficient use of natural resources and avoiding the costs of environmental damage. {11.3.3}

**Involving alliances, clubs and non-State actors in policy design may provide opportunities for peer pressure to overcome institutional reluctance.** Hybrid governance, combining different modes and instruments of governance, can help mutually strengthen institutional responses. There is no ‘one size fits all’ governance structure, however. As for policy effectiveness, different approaches have been proposed to gauge institutional effectiveness, involving both qualitative and quantitative methods. Increasingly important in international environmental policy discourse is the role of non-State actors such as local governments, cities and civil society organizations. As the 17 SDGs are intended to be fully integrated and universal, several countries are now grappling with the task of devising the most effective institutional arrangements to address the desired vertical and horizontal policy integration. {11.4.2}

Finally, the importance of good policy design cannot be overstressed. Some common elements are: (i) setting a long-term vision and avoiding crisis-mode policy decisions, through inclusive, participatory design processes; (ii) establishing a baseline, as well as quantified targets and milestones; (iii) conducting *ex ante* and *ex post* cost–benefit or cost-effectiveness analysis to ensure that public funds are being used most efficiently and effectively; (iv) building in policy monitoring regimes during implementation, preferably involving affected stakeholders; and (v) conducting post-intervention evaluation of the policy outcomes and impacts, to close the loop for future policy design improvements. {11.5}

## 11.1 Introduction

Academic and practical or policy advice-related research asks important questions about environmental policy. However, the literature still struggles with common conceptual and empirical challenges, including:

- diverse conceptualizations and measurements of policy, which frustrate generalization;
- poorly understood dynamics of policy change and stability; and
- complex effects of policy design choices.

Overall, these common challenges impede the comparability of findings across environmental policy fields, risking somewhat narrow approaches and perspectives.

One potential starting point for overcoming this narrow focus is a renewed interest in policy design. Are there common elements of 'good' policy design that are transferable across problem domains? How do policymakers search for effective policy precedents, and how does this search lead to policy diffusion across countries and across problem domains? How does the theoretical understanding of policy design contribute to policy practice?

This section examines the literature and teases out some lessons learned for validation by the policy domains/instruments and governance arrangements and associated case studies in Chapters 12–17 of Part B (**Figure 11.1**). Essentially, it addresses the top portion of Figure 11.1, while Chapters 12–17 explore the lower half. Figure 11.1 illustrates the importance of going beyond an analysis of individual policy instruments when trying to determine policy effectiveness. At the policy design stage, policymakers should examine how an environmental policy will either support or conflict with policies in other sectors, and vice versa. Various policy integration tools are available to contribute to this design requirement. Within the environmental policy mix, policymakers should ensure that any new policy is coherent with and supportive of the

intended policy outcomes. Policymakers at multiple levels of governance may also examine experience from other countries, subnational areas or corporations, leading to policy diffusion across borders and over time. In subsequent chapters, this experience is examined from the perspective of multiple case studies, to tease out explanations of why particular policy approaches appear to have been more or less effective, as well as to analyse policy-sensitive indicators.

## 11.2 Policy design

The challenges described above, relate both to the spatial and temporal dynamics of policy change and to the complexity of how policy instruments interplay within a policy mix. These have led to a renewed interest in questions of policy design (Howlett and Lejano 2013). The literature acknowledges the complexities of design elements in dense policy mixes (Howlett and Cashore 2009; Howlett and del Rio 2015; Young 2017), and it also recognizes that the compliance system highly influences it (Grey and Shimshack 2011). However, as the research agenda develops, approaches for institutional diagnosis (Young 2008; Ostrom 2009), empirical assessment and analysis of policy change (Jabbour *et al.* 2012; Knill, Schulze and Tosun 2012; Schaffrin, Sewerin and Seubert 2015) have been increasingly applied to systematic, more quantitative analysis of policy (mix) dynamics (Voigt 2013). Young (2008) argues that ecosystem properties and problems, policies, practices and players need to be considered as elements for regime design under a diagnostic analytical approach that tries to match institutional arrangements to those properties and structures. Ostrom (2007) takes a similar approach and builds a framework that contains many types of resource properties across multiple scales, including local.

Regarding policymakers' decision-making, there is an emerging consensus that policy design is at least as important as policy instrument choice for both individual policy effectiveness and for the effectiveness of the overall policy mix (Mitchell 2002; Yin and Powers 2010; Flanagan *et al.* 2011; Kemp and Pontoglio 2011). For example, technology-specificity—i.e. where a policy

**Figure 11.1: Conceptual outline of policy effectiveness analysis**

explicitly differentiates between different available technologies that address a given policy problem—is increasingly applied in the analysis of low-carbon technology deployment policies (e.g. Schmidt *et al.* 2016). Yet, integrating the various perspectives on policy design (e.g. from implementation research or governance studies) remains challenging. Still, literature on policy dynamics and policy mixes, on policy design and policy effectiveness and on long-term intervention logics is increasingly available (Young 1999; Miles *et al.* 2002; Howlett and Rayner 2013; Mees *et al.* 2014).

When trying to tackle the various pressing environmental problems outlined in Part A, a policy design perspective would be very helpful. Analysts and policymakers alike need to better understand the temporal dynamics of policy change, how and why specific policies work (or not) and how policy choices interact in an increasingly complex mix of policies. Ideally, this would help to improve the design of policies that create positive feedback loops (including *ex post* impact assessment), eventually changing the underlying instrumental logic of a policy mix (Figure 11.2).

### 11.2.1 Spatial dynamics: policy diffusion across borders

Policy diffusion research aims to understand how and why policies spread across borders and are adopted and designed by different jurisdictions. The academic literature, primarily from the field of political science, tends to focus on drivers of the spatial diffusion of policies (Tews, Busch and Jorgens 2003; Holzinger, Knill and Sommerer 2011; Graham, Shipan and Volden 2013; Matisoff and Edwards 2014), and much less so on what policies have actually diffused and when (Jordan and Huitema 2014a). In the environmental policy research literature, policy diffusion featured prominently in the 2000s

and early 2010s. The main focus of this research was on environmental regulations (Knill, Schulze and Tosun 2012) and renewable energy policy (Alizada 2017). The former was helped by the availability of a large data set of regulatory standards covering primarily emissions (Heichel *et al.* 2008), while the latter was driven by the debate about the effectiveness of feed-in tariffs and renewable portfolio standards as renewable energy deployment policy tools. Generally, these studies focused either on the macro-level characteristics of policies (e.g. policy instrument types), as in Stadelmann and Castro (2014), or on very specific regulatory standards (e.g. NO<sub>x</sub> or SO<sub>2</sub> emissions standards for large combustion plants) as in, for example, Liefnerink *et al.* (2009); Holzinger, Knill and Sommerer (2011). In relation to renewable energy, four possible mechanisms of policy diffusion—emulation, suasion, learning and competition—were examined (Alizada 2017). Suasion and emulation were found to be more common than learning and competition.

More recently, there has been an explosion in climate change-related policies in both developed and developing countries. Over the period 1998–2010, there was a fivefold increase in national climate laws, and by 2012 these laws covered 67 per cent of all emissions (Jordan and Huitema 2014b).

There is little research, however, on the post-adoption dynamics of diffused policies. Only isolated studies (e.g. Biesenbender and Tosun 2014) analyse how these policies are adapted in new jurisdictions—i.e. how they are modified subsequent to the initial diffusion. The European Union's emissions trading scheme is a good example of the difficulties in adjusting policy from one jurisdiction to another (Cass 2005). Post-adoption dynamics may even undermine the intended policy impact and policy coherence (Jordan and Huitema 2014a).

Figure 11.2: The policy cycle

Source: European Environment Agency [EEA] (2006)

Some publicly available data sets aim to help chart the diffusion of environmental policies, particularly related to climate change and, more specifically, to renewable energy policy. The London School of Economics' Climate Change Laws of the World Database (Nachmany *et al.* 2017), for example, compiles information on national-level climate policies ranging from adaptation to mitigation to transport. Similarly, REN21's Global Status Report charts the use of renewable energy policies across a large sample of national and subnational jurisdictions. International organizations, such as the International Energy Agency (IEA), also collect information on renewable energy-related policies in use across a large sample of jurisdictions. The quality of all these data sets, though, varies, as does the method of collection, categorization of policies and the level of detailed policy information included. This problem relates to what has been coined the "dependent variable problem in the study of policy change" (Howlett and Cashore 2009)—i.e. the underlying challenge of how to assess policy output systematically across cases. While efforts have been made to develop a common methodology for measuring policy output in a comparable way (e.g. Knill, Schulze and Tosun 2012; Schaffrin, Sewerin and Seubert 2015), these approaches are only slowly being taken up, and most policy dynamics analysis continues to apply diverse or ad hoc concepts and measurements of policy output. Thus, despite prolonged interest in the topic and efforts to provide systematic policy information, knowledge of the spatial diffusion of environmental policies, especially outside the specific policy field of renewable energy, remains limited.

### 11.2.2 Temporal dynamics: policy change over time

If and how policies change over time and what factors drive these changes are important topics in the academic literature. The different approaches for understanding policy change can be categorized, on the one hand, in path-dependency literature, which stresses that early policy decisions lock in policy choices and that most policies only change incrementally after they are implemented (Pierson 2000). The main reason for such stability is thought to be positive feedback, through for example, policy learning that creates and sustains self-reinforcing processes around a policy. On the other hand, the punctuated equilibrium approach seeks to explain how otherwise stable policies can unravel in a sudden burst of abrupt, non-incremental change (Baumgartner and Jones 2009; Colgan, Keohane and Van de Graaf 2012). The main driver of these punctuations is thought to be external shocks that tilt the otherwise stable balance of positive and negative feedbacks towards a new equilibrium. One example of such a shock could be a legal case that challenges the legitimacy of the environmental policy. A punctuation could also create opportunities for environmental policies; for example, the Fukushima disaster in Japan may have led to Germany's policies to phase out nuclear energy (Wittneben 2012).

Both approaches have been applied in the analysis of environmental policy change (e.g. Daugbjerg 2003; Repetto 2006), although the applications have mostly concentrated on large programmes in particular policy areas, such as agriculture. Recent literature has argued that focusing exclusively on positive feedback or on the catalytic effect of external shocks is not very helpful for intentionally designing policies that can both create positive feedback and withstand sustained negative feedback and external shocks (Jordan and Matt 2014).

The complexity of environmental problems can also increase the risk of 'policy under-reaction' by decision-makers, since it is difficult for policymakers to accurately estimate risks (Maor 2014). To avoid risks from taking decisions with unwanted side effects, policymakers tend to delay decisive action as long as possible and, confronted with external shocks, choose symbolic action rather than effective policymaking (Howlett 2014). There are a number of suggestions for strengthening the importance of the environment within States to overcome such shortcomings (Kloepfer 1989; Calliess 2001; Eckersley 2005; Jänicke 2007); however, this has not happened so far: the importance of the environment is not institutionalized as a priority but competes with other goals of governments.

Against this background, research is increasingly turning to policy design (Howlett and Lejano 2013) and seeks to understand how policy design choices can create policy change—i.e. how steps of incremental policy change can, over time, build up to create transformational change. Policies that are 'sticky' (i.e. persistent) but not 'stuck' (i.e. unresponsive to changing conditions) and that create positive feedbacks are seen as a potential way to increase the effectiveness of environmental policies (Jordan and Matt 2014). The Paris Agreement on climate change and its ratcheting-up mechanism is a prominent example of this concept (Falkner 2016). The need for such a forward-looking approach to policy design can be seen in policy fields that are troubled with complexity, as is the case for most environmental problems (Levin *et al.* 2013). The design of international regimes heavily influences their effectiveness—even more importantly than the type of underlying problem. In other words: an easy problem is not solved if an international regime is poorly designed (Young 2011). Given the context dependency of policies and regimes, a careful diagnosis of the appropriateness of their design is essential (Young 2011).

Policy innovation can be regarded as a mix of invention (new or novel approaches), diffusion (transfer and adoption) and monitoring of their effects (outcomes, impacts and possibly disruption) (Jordan and Huitema 2014b). The literature on polycentric governance suggests that multiple innovative policies should be implemented as a form of quasi-experiment, with best practices emerging from the monitored effects. It has been argued that governance at the lowest possible level minimizes free-riding as a motivation, and that monitoring is easier in smaller entities, e.g. communities (Marshall 2009). However, on a global scale, polycentric governance could lead to free-riding by governments, for example in the absence of a global regime, governments could be tempted to avoid actions while benefiting from mitigation efforts by others (Ostrom 2010). However, the role of policy entrepreneurship, and the contribution of civil society, in motivating policy shifts should not be underestimated.

Policy innovation, however, is not necessarily the most effective pathway to policy packaging, as tried and true command and control and economic incentive policies may deliver most of the impact (Hildén, Jordan and Rayner 2014; Jordan and Huitema 2014a). Greater focus on policy coherence, successful implementation and compliance may prove that traditional policy approaches still work effectively. Innovative policies may bring new implementation and compliance challenges which existing institutions are not well equipped to handle.

### 11.2.3 Policy effectiveness through improved design

In the past, attempts to measure policy effectiveness assumed there was a one-to-one correlation between an environmental policy and its outcomes (Weber, Driessen and Runhaar 2013). In some cases, this may be warranted, such as a government command and control policy to remove lead from petrol or from paint (see the subsequent discussion of policy-sensitive indicators). However, in most of the case studies in Chapters 12-17, attributing environmental outcomes to specific policies is shown to be challenging. Counterfactual scenarios (i.e. without policy) cannot be implemented experimentally, for practical and ethical reasons among others, as it is not justifiable to expose one group to a policy against a harmful pollutant and not others (Niles and Lubell 2012).

For these reasons, evaluation of policy effectiveness often comes down to the use of expert judgement (**Figure 11.3**) (EEA 2001; Egger *et al.* 2015). Figure 11.3 shows that not all energy efficiency policies are ranked equally, and a significant proportion of experts believe some policies are not effective at all. Although there are some limitations to measuring policy effectiveness, some important insights have emerged, not only from the use of statistical procedures to separate the effects of individual variables but also from the application of alternative techniques, such as Qualitative Comparative Analysis (QCA), designed to identify combinations of factors that operate together, to determine the effectiveness of policies (Breitmeier, Underdal and Young 2011). Ideally, a combination of quantitative and qualitative assessments will be most reliable in assessing policy effectiveness (Egger *et al.* 2015).

Some policy design tools that can supplement expert judgement are:

- cost-benefit analysis and cost-effectiveness analysis, both of which can be used *ex ante* or *ex post* (Interviews, Gorlach and Newcombe 2007);
- regulatory impact analysis (Organisation for Economic Co-operation and Development [OECD] 2008);
- benchmarking or distance to target (Uslu, Mozzaffarian and Stralen 2016); and
- content analysis or pattern matching (Di Gregorio *et al.* 2017).

Of course, environmental problems are essentially social constructs, and what appears as an environmental problem to one group may not be seen as a problem by another group with different interests. Therefore, in designing effective policies, framing of the 'problem' is extremely important. For example, framing climate change as an issue involving employment and security, as exercised in Europe, may be more effective than simply discussing it as a technical or scientific issue. Changing the approach to economic development from 'grow now, clean up later' may be an important shift in environmental policy design in several developing countries.

### 11.2.4 Policy mixes

As indicated in Chapter 10, within the environmental domain a key lesson learned is to carefully craft a mix of policies that are well aligned with the overall policy objective (OECD, IEA, Nuclear Energy Agency [NEA] and International Transport Forum

**Figure 11.3: Results of expert perspectives on European energy efficiency policies**

Source: Egger *et al.* (2015)

[ITF] 2015) and then monitor the actual effects to determine best practice. For example, climate change mitigation policy objectives will need a comprehensive mix of carbon pricing, support for energy efficiency and renewable energy, phasing out fossil fuel subsidies, innovation policies, preventing locked-in technology and changes in consumer behaviour, among others (Hood 2011). Too often policies are not well aligned and may even be in conflict, so solving misalignment and ensuring that policies are mutually reinforcing may be one of the best ways of achieving environmental improvement (OECD *et al.* 2015).

Policy analysis literature increasingly recognizes the need to view policies not in isolation but to consider each policy in its wider context among a mix of other policies. Policy mixes are generally thought of in relation to specific policy fields (e.g. the renewable energy policy mix). Their quality is traditionally assessed in qualitative terms and draws on a set of concepts, such as

- i. consistency of multiple policy instruments (i.e. instruments' ability to reinforce rather than undermine each other),
- ii. coherence of multiple policy goals (i.e. goals not contradicting each other) and
- iii. congruence of multiple policy goals and instruments (i.e. their ability to work together in a unidirectional fashion) (Howlett and Rayner 2013; Kern, Kivimaa and Martiskainen 2017).

While these concepts are widely used, they are neither consistently defined nor is there an accepted common practice of assessment, leading to a lack of empirical analysis of patterns of policy mixes (Howlett and del Rio 2015). Other than a rather broad understanding that some types of policy instruments do not necessarily work well together, the interplay of policy instruments in a mix is not well understood. One main reason for this is the persistent challenge to adequately and systematically assess and evaluate individual policies (Capano and Howlett 2009; Howlett and Cashore 2009)—i.e. the building blocks of complex policy mixes—let alone how they mix with other policies. Only recently has research begun to tackle these important challenges, either by conducting policy mix analysis based on comprehensive data sets (Schmidt and Sewerin 2018), or by modelling the interplay of policy instruments. These models, however, are generally limited to the interplay of two or three policies, whereas the real-world mix, consisting of many more policies, is usually more complex.

### 11.3 Policy integration

Environmental objectives cannot be realized by implementing a mix of environmental policies alone; they need to be integrated in non-environmental policy sectors too. This is underpinned in the integrated approach of Agenda 2030 and the Sustainable Development Goals (SDGs). However, environmental ambitions often clash with other sectoral goals—for example, when the utilization of natural resources by the energy sector, agriculture industries or for building infrastructures clashes with efforts to conserve those natural resources. A concept that promotes the environment in other policy sectors, and recognized in previous GEO assessments, is 'environmental policy integration' (EPI) (Lay *et al.* 2017). EPI aims to settle such conflicts between environmental and other policy objectives and has been discussed in the scientific literature (Nilsson

*et al.* 2012; Runhaar, Driessen and Uittenbroek 2014) and debated in policy contexts from early on (Mullally and Dunphy 2015). It led to the introduction of a wide range of institutions, processes and instruments for its implementation (Jacob *et al.* 2008). The principle of EPI also contributed to change in policy discussions which again affected policy outcomes (Scarse and Ockwell 2010; Espinosa *et al.* 2017). Others suggest that EPI needs to go further and demand the "incorporation of environmental objectives into all stages of policy-making in non-environmental policy sectors, with a specific recognition of its role as a guiding principle for the planning and execution of policy" (Lafferty 2004, p. 201). This level of ambition is not achieved in reality, as policy incoherence and competition typically prevail, pointing to the limitation of the institutions, instruments and processes that have been introduced to promote EPI.

It is not always clear how institutional and socio-economic conditions associated with other policy domains degrade the environment, making it difficult to understand which EPI strategies would work to mitigate this degradation (Runhaar, Driessen and Uittenbroek 2014). Systematic evidence is lacking on how sectors such as agriculture, transport, urban planning or water management incorporate environmental concerns and standards to prevent, reduce or mitigate any harmful environmental effects. Nonetheless, one necessary but insufficient condition for policy integration is political leadership and the acknowledgement of co-benefits across multiple policy domains (Persson 2007; Jordan and Lenschow 2010).

#### Policy coherence

A closely related concept to policy integration is policy coherence: the promotion of mutually reinforcing policy actions creating synergies towards achieving objectives in multiple sectors. Attempts at better coherence include the development of national sustainable development strategies and various road maps, such as those developed by the European Commission or the 'better regulation' agenda pursued by both the European Union (EU) and the OECD (European Commission 2010). Here too, policy leadership and co-benefits are necessary but insufficient. In 2016, the OECD elaborated a framework of policy coherence for sustainable development based on eight building blocks:

- i. political commitment and leadership at the highest level;
- ii. integrated approaches to implementation;
- iii. an intergenerational time frame;
- iv. analysis and assessments of potential transboundary effects;
- v. policy and institutional coordination;
- vi. local and regional involvement;
- vii. stakeholder participation; and
- viii. monitoring and reporting (OECD 2017).

A major example of an attempt at environmental integration and coherence within the United Nations environmental umbrella are the SDGs (United Nations General Assembly [UNGA] 2015). The SDGs encompass major environmental areas such as climate change, chemical pollution, waste, and marine and terrestrial ecosystems, but they also include social, economic and institutional development objectives applicable to both low-income and high-income countries, such as access to food, water, sanitation, energy, health,

education and justice, and the development of infrastructure, cities, employment and growth (Nilsson and Persson 2017). The SDGs mark a historic shift for the United Nations towards a unique 'sustainable' development agenda after a long history of trying to integrate economic and social development with environmental sustainability. Before the SDGs, international agreements were more fragmented and sectoral, and while environmental integration was regularly mentioned on paper, it was rarely translated into practice. Of course, the effectiveness of the holistic, indivisible approach recommended for the SDGs remains to be seen.

Chapters 12-17 identify examples of regulatory and other policy instruments that have demonstrated some utility for policy integration and coherence. Regulatory policies have emerged in most countries over the last two decades under the umbrella of so-called 'better regulation policies' (Turnpenny *et al.* 2009; De Francesco 2012; Adelle *et al.* 2015). In many countries these have led to the establishment of institutions and the adoption of instruments and processes, such as regulatory impact assessments, participatory approaches and *ex post* evaluation. Initially, this was motivated by concerns to cut the costs of regulation and deregulation. However, in some countries these instruments were broadened in their scope and used to promote the integration of concerns about sustainable development into policymaking (Bäcklund 2009; Adelle and Weiland 2012; Renda 2017).

The SDGs (e.g. target 17.4) emphasize the need to "enhance policy coherence for sustainable development" (OECD 2016). A key lesson learned is to ensure policy coherence between different levels of governance and across economic, social and environmental domains. Accordingly, it is not sufficient to consider environmental policies as separate from macroeconomic or sectoral policies, which often act as drivers of environmental degradation, or from social policies that attempt to address the human impacts of environmental damage. It is possible to see in the case studies in Chapters 12-17 that these other policies often act as enabling or constraining factors in achieving environmental policy effectiveness. When analysing policy coherence, policymakers also need to consider long-term as well as short-term impacts (OECD 2016).

### 11.3.1 Integration of environmental aspects in regulatory policies

Integrating environmental concerns and policy objectives into different policy domains comprises the cornerstone of EPI (Runhaar, Driessen and Uittenbroek 2014). Ensuring that such concerns and policy objectives are incorporated in the development of legislation may prove critical in promoting EPI (Jacob *et al.* 2011). Many countries have adopted approaches/instruments to assess the potential impacts of proposed legislation on stakeholders, economic sectors and the environment (Radaelli 2009; Jacob *et al.* 2011; Adelle and Weiland 2012; Adelle *et al.* 2016). In OECD countries, *ex ante* assessment of regulatory policies has become a standard administrative procedure. For example, the Netherlands demands such an assessment for all new laws, orders in councils and proposed amendments; in Canada, a key part of the regulatory process is describing how government actions

affect citizens; and in Australia, it is mandatory for proposed legislation and tax-related reforms to include regulatory impact statements and assessment (Jacob *et al.* 2011).

To effectively address climate change, Di Gregorio *et al.* (2017) suggest that climate policy integration needs:

- i. policy coherence between mitigation and adaptation;
- ii. policy coherence between climate change and development objectives;
- iii. vertical policy integration by mainstreaming climate change into sector policies; and
- iv. horizontal policy integration through cross-sectoral coordination.

These multiple dimensions and governance arrangements make effective policy design particularly difficult.

Assessment requirements and practices vary across countries, as do the extent to which environmental aspects are considered (Jacob, Volkery and Lenschow 2008; Jacob *et al.* 2011). However, among OECD countries, assessments of regulatory policy share four key aspects or objectives:

- i. assessment of impacts;
- ii. integration of policies;
- iii. promotion of transparency; and
- iv. the improvement of accountability (Ritzka 2016).

Further, regulatory impact assessment is believed to improve policy coherence and minimize policy conflicts, ultimately contributing to regulatory quality and good governance (Hertin *et al.* 2009).

Usually, regulatory impact assessment involves several stages, with environmental aspects being relevant to all of them (Table 11.1). Integrating environmental aspects in assessments of regulatory policies involves tools for gathering and analysing data about the likely outcomes and impacts of policy options. These tools are used to generate and analyse data on specific impact areas (e.g. socio-economic, biophysical models and integrated models), to integrate and aggregate data, such as scenario tools and cost-benefit analysis, and to involve stakeholders in policy development (Jacob *et al.* 2011).

**Table 11.1: Typical stages of regulatory impact assessment**

- ❖ Selection of policy proposals to be subject to assessment
- ❖ Description of the problem and the objective of the proposed regulation
- ❖ Description of the baseline scenario
- ❖ Identification of policy options to be assessed
- ❖ Assessment of options, including the anticipated impacts in the different areas as well as the weighting and aggregation of different impacts
- ❖ Consultation of stakeholders and other interested parties on the assessment results
- ❖ Review of the quality of the assessment

## Box 11.1: Carbon valuation as part of United Kingdom of Great Britain and Northern Ireland's policy assessment

In 2002, the United Kingdom of Great Britain and Northern Ireland Ministry of Economics and Finance (HM Treasury) and the Department of Environment, Food and Rural Affairs (DEFRA) jointly published a report on how to integrate the social costs of carbon emissions into policy decisions. Since 2003 the Greenhouse Gas (GHG) Impact Assessment has been mandatory as part of the broader policy assessment process (United Kingdom, Department for Business Innovation and Skills [BIS] 2010, p. 73). It uses cost–benefit analysis and requires assessment of all policy initiatives.

The rationale for estimating GHG emissions that arise from potential government policies is “to inform key climate change policy decisions”. Policies shall be developed to meet United Kingdom of Great Britain and Northern Ireland short and long-term CO<sub>2</sub> reduction targets, which establish choices between competing objectives (BIS 2010.). GHG tests are applied within the overall cost–benefit analysis to assess whether a policy is cost-effective in comparison with other alternatives (*ibid.*, p. 91).

The approach of estimating the social cost of carbon was reviewed in 2007. As a result, it was replaced by the shadow price of carbon to allow for consideration of then more recent evidence drawn from the Stern Review. In 2009, the shadow price of carbon was in turn revised and replaced by a target-consistent approach (United Kingdom, Department of Energy and Climate Change [DECC] 2009, p. 5).

Source: Jacob *et al.* (2011).

The assessment of the social costs of carbon in the United Kingdom illustrates the approach and the associated tools described above (**Box 11.1**). The United Kingdom of Great Britain and Northern Ireland is considered to be the country with the longest experience with climate impact assessment, featuring one of the most elaborate approaches to policy assessment, as well as specific legislation to support this work (the United Kingdom of Great Britain and Northern Ireland Climate Change Act) (Jacob *et al.* 2011).

Considering the variety of approaches and tools for assessing regulatory policies, Adelle *et al.* (2011) suggest that there is no ‘one way’ or ‘best way’ of conducting these assessments. However, some jurisdictions may be regarded as exemplars, such as the EU, for the high level of integration of its approach and consideration of social, economic and environmental dimensions (Adelle *et al.* 2016). Based on a review of regulatory policy assessments in selected OECD countries, Jacob *et al.* (2011) suggest how to better consider environmental aspects in assessments of regulatory policies, including:

- ❖ taking into consideration environmental costs and benefits when regulating economic activities;
- ❖ undertaking early assessment, notification and participatory approaches to minimize conflicts between departments and with stakeholders and increase the social robustness of proposals;
- ❖ using well-established models, such as those available for climate change, emission of harmful substances, and land use;
- ❖ introducing institutional requirements, including mechanisms for quality control, transparency and consultation; and
- ❖ building capacity of environmental departments and agencies to perform or support regulatory impact assessment.

### 11.3.2 Other policy integration tools

There are other tools for policy integration besides the tools of regulatory policies such as regulatory impact assessments. Environmental impact assessments (EIAs) are used around the world, especially on major projects such as dams and other infrastructure (Morgan 2012). EIA has been used steadily over the last two decades and is recognized in a large number of

international agreements (for example, the Espoo Convention, Ramsar Convention, Aarhus Convention, UNFCCC, UNCLOS and the Protocol on Environmental Protection to the Antarctic Treaty (Madrid Protocol)).

Strategic environmental assessment (SEA) was elaborated as an extension of EIA's principles, procedures and methods to higher levels of decision-making (Lee and Walsh 1992). SEA is seen as a tool able to evaluate a set of policies with broader lenses and within a more systematic and comprehensive process of evaluating the environmental impacts of a policy, plan or programme and its alternatives. SEA is the process by which environmental considerations are fully integrated into the preparation of plans and programmes prior to their final adoption. The objectives of the SEA process are to “provide for a high level of protection of the environment and to promote sustainable development by contributing to the integration of environmental considerations into the preparation and adoption of specified Plans and Programmes” (United Kingdom Environmental Protection Agency [UK EPA] 2018).

For the European Commission, the SEA procedure can be summarized as follows: “an environmental report is prepared in which the likely significant effects on the environment and the reasonable alternatives of the proposed plan or programme are identified. The public and the environmental authorities are informed and consulted on the draft plan or programme and the environmental report prepared.” The EU ratified the Protocol on Strategic Environmental Assessment in November 2008. The SEA Directive (Directive 2001/42/EC) transposes the Protocol in EU legislation (European Commission 2001).

There is little evidence on the actual outcomes of applying the various tools of policy integration and attempts to measure the level of policy integration, and most examples of evaluations were undertaken in the context of Europe. For example, in countries where environmental liability is weakly developed, EIA/SEA tools may have limited effectiveness (United Nations Economic Commission for Africa 2005; Kotze and Plessis 2006; Gitari *et al.* 2016).

Among the few exceptions is the Publishing and the Ecology of European Research (PEER) project (Mickwitz *et al.* 2009). The study assessed the extent of climate policy integration in different European countries, policy sectors and, in some

cases, regions and municipalities. The assessment is based on five criteria: inclusion, consistency, weighting, reporting and resources. The report also analyses measures and means for enhancing climate policy integration and improving policy coherence in each country of many policies, but mostly centred on one or two, and on some regions and municipalities. With this work it was possible to draw some conclusions, such as the fact that reducing emissions has become a key political issue, and climate change is widely integrated into government programmes. The selected countries recognized the need for climate policy integration if the more ambitious climate change mitigation commitments are to be achieved.

In terms of policy integration, one lesson from PEER is that cities and municipalities have also integrated climate aims in their strategies and in specific measures, and their goals are sometimes more ambitious than those of their respective countries. The study also highlights that effective climate policy integration will require sufficient resources in the form of knowledge and money. Without these resources, there will be no realistic possibility of truly recognizing the links between general or sectoral policies and climate change or of finding alternatives and implementing them. According to the PEER project, given the great complexity of the socio-economic processes that result in GHG emissions, as well as those of adapting to a changing climate, policies need to be based on learning.

The increasing role of non-State actors (e.g. cities, civil society groups, etc.) in global climate governance is contributing considerably to the advancement of mitigation efforts. The example of the announcement of the United States pulling out of the Paris Agreement demonstrates that climate policy integration is not a one-way path but is reversible. Although the announcement possibly had no adverse impacts on the activities of US communities and firms to reduce GHG emissions, it still points to the need for more robust institutionalization.

Another example of a policy integration tool is the EU evaluation of its Common Agricultural Policy (CAP) compared to its energy policies. The CAP dates back to 1962 and is one of the oldest policies with the aim of providing price support and food security. In 2013, CAP reforms placed sustainable development as a core objective of the programme. Policy integration thus evolved from a traditional position that assumed agricultural and environmental objectives were intrinsically aligned, to a broader recognition that explicit environmental policy integration is necessary. Still, climate change considerations are conspicuously absent from the agricultural sector policy efforts.

By contrast, energy policy development efforts have introduced environmental considerations because of explicit environmental concerns, and more recently, the growing awareness of climate change has intensified efforts to integrate environment and energy policies. The policy integration approach for energy has notably shifted from one of sustainable development in the late 1990s to one where the climate change agenda has all but captured the environmental dimension of the sector, leading to such apparent anomalies as the promotion of 'sustainable nuclear energy' and a possible overemphasis on the need for biofuels. This lack of consistency across policy boundaries makes successful environmental policy integration more difficult and may lead to conflicting policy instruments where the domains intersect—for example, biofuels in the case of energy and agriculture (Mullally and Dunphy 2015).

Another notable example is the Nepal initiative to include climate change not only in environmental matters but as a major consideration in all development planning. The Climate Public Expenditure and Institutional Review (Government of Nepal *et al.* 2011) reviews the financial management systems as well as the institutional arrangements and policy directives for allocating and spending climate change-related finance. This study examined the early emphasis being given to climate change programming within Nepal and acknowledges the role played by communities in the entire process, including civil society, the private sector and international support. The main findings include the lack of institutional collaboration and capacity-building to integrate policies across the different ministries. In addition, the fragmentation of budget implementation frustrates the coordination of expenditures to facilitate and promote the best outputs and outcomes, leading to an attempt to build climate change expenditures into the national chart of accounts.

A final example of EPI relates to the global trade regime. The EU attempted to explicitly integrate environmental concerns into its trade agreement strategy in 2010, with the Communication on Trade, Growth and World Affairs, a part of the EU's 'Europe 2020' strategy. The EU also tried again in 2012, with the Communication on Trade, Growth and Development (Morin, Pauwelyn and Hollway 2017). As the controversies on the recent negotiations on trade agreements with Canada, the United States of America and Japan demonstrate, their effectiveness is under dispute.

At the multilateral level, the EU is actively involved in advancing the mandate of paragraph 31 of the Doha Declaration on the liberalization of environmental goods and services in the

regular and special sessions of the World Trade Organization (WTO) Committee on Trade and Environment, albeit with little progress so far. In 2014, 14 WTO members (including the EU), representing more than 80 per cent of world trade in environmental goods, launched the Green Goods Initiative which, as a first step, aims to eliminate tariffs on a broad list of green goods. The objective of the ongoing Environmental Goods Agreement (EGA) negotiations is to make high-quality environmental goods and technologies available at cheaper cost.

The EU, for example, also incorporates environmental provisions into bilateral and regional preferential trade agreements in the form of Trade and Sustainable Development (TSD) chapters. These provisions *inter alia* commit EU trade partners to ratify and implement key multilateral environmental agreements (MEAs) domestically and enforce them effectively. They are integrated into the agreement negotiation process through sustainability impact assessments (SIAs). SIAs are independent assessments carried out by external consultants but rely on input from stakeholders. Both the EU and civil society then closely monitor partners' implementation of TSD environmental provisions. Since such provisions may represent a costly commitment, partners may then demand that similar environmental provisions are included in their subsequent trade agreements with third parties (Milewicz *et al.* 2016). The EU has unilaterally established the Generalized Scheme of Preferences (GSP) to allow developing-country exporters to pay lower duties on exports to the EU. The GSP+ arrangement is intended to build the capacity of vulnerable countries to integrate environmental concerns into their sustainable development plans by offering them additional trade preferences.

This relationship between trade and the environment is apparent in other ways. For example, environmental policies may impede some undesirable forms of trade, and trade policies may water down potentially stronger international environmental policies. Trade policy measures appear in a range of environmental instruments, such as the restrictions on trade in endangered animal and plant species, illegal timber, illegal, unreported and unregulated (IUU) fishing, chemicals of regional or global concern and ozone-depleting substances. Generally, the influence of environmental non-governmental organizations (NGOs) and their concerns over trade policies remains limited (Dür and De Bièvre 2007).

In summary, EPI and associated tools have been used by governments trying to include environmental concerns in other sectoral policies of interest. However, there is a lack of evaluation of actual outcomes and impacts of EPI and major challenges persist: institutional fragmentation, lack of capacity-building, the difficulty of stakeholder participation and even integration with other environmental issues beyond climate change.

### 11.3.3 Co-benefits: findings on the impacts of environmental policies on economic growth, innovation and employment

An important argument in favour of EPI is the economic and social co-benefits that can be expected or demonstrated as a result of implementing environmental policies. These may include additional economic growth from innovation, savings from more efficient use of natural resources and avoiding

the costs of environmental damage. However, the concept of co-benefits is contested because it mostly ignores political and 'North–South' aspects (Mayrhofer and Gupta 2016).

More specifically, policies that integrate environmental aspects in key economic sectors benefit from synergies and promote long-term growth by mitigating scarcities. In this regard, it is estimated that a green investment of 2 per cent of global gross domestic product (GDP) would deliver long-term growth over 2011–2050 that could be at least as high as an optimistic business-as-usual scenario, while minimizing the adverse impacts of climate change, water scarcity and the loss of ecosystem services (United Nations Environment Programme [UNEP] 2011).

Well-crafted policies that integrate environmental concerns can in many cases promote innovation (especially technological innovation, but also policy and institutional innovation) (Ambec and Barla 2002; Ambec *et al.* 2013). This is based on the following premises (Porter and van der Linde 1995, pp. 99–100, cited in Ambec *et al.* 2013):

- ❖ "...[R]egulation signals companies about likely resource inefficiencies and potential technological improvements."
- ❖ "... [R]egulation focused on information gathering can achieve major benefits by raising corporate awareness."
- ❖ "... [R]egulation reduces the uncertainty that investments to address the environment will be valuable."
- ❖ "... [R]egulation creates pressure that motivates innovation and progress."
- ❖ "... [R]egulation levels the transitional playing field. During the transition period to innovation-based solutions, regulation ensures that one company cannot opportunistically gain position by avoiding environmental investments."

In this context, market-based and flexible instruments such as environmental taxes and tradable emissions are believed to be more conducive to innovation by allowing business to determine the best ways to achieve compliance (Ambec *et al.* 2013). Further, there is an increasing tendency for over-compliance by businesses seeking to gain competitive advantage and/or maintain their social licence to operate (Ford, Steen and Verreyne 2014). Market-based instruments are, therefore, essential for triggering the efficiency-based green economy process (EEA 2014). Nevertheless, a green economy approach and market-based instruments focusing on efficiency are frequently criticized on the grounds of poor consideration of social equity—for example, by having distributional effects that disadvantage poor people.

Environmental policies can also have a positive impact on employment, particularly in the context of economic activities integrating the environmental dimension; these include renewable energy, construction, transport, agriculture, forestry and recycling and waste management (UNEP 2011; OECD 2017). Renewable energy is a critical source of employment growth; in 2016, it was estimated that this sector was responsible for 8.1 million jobs globally. Projections indicate that this figure may reach up to 20 million jobs by 2030: 2.1 million jobs in wind energy production, 6.3 million in solar photovoltaics and 12 million in biofuels-related agriculture and industry (OECD 2017). Other sectors, such as agriculture, buildings, forestry and transport are predicted to see job growth in the short, medium and long term exceeding their comparable

business-as-usual scenarios, as a result of a more resource-efficient and low-carbon economy (UNEP 2011). For example, China, which leads global employment in renewable energy, is predicted to generate at least 4.5 million jobs as a result of greening in sectors such as transport and forestry (Pan, Ma and Zhang 2011). Other studies, which take into account possible losses in other sectors and calculate the net effects of jobs created from environmental policies, are less optimistic, but overall evidence suggests that the net effects are at least not negative (Telli *et al.* 2008; Lin and Jiang 2011; Willenbockel 2011; Jacob, Quitzow and Bär 2015).

## 11.4 Effectiveness of international and multilevel governance

### 11.4.1 Enduring conceptual challenges of institutional effectiveness

Of course, proper framing of an environmental problem and good policy design form only part of the policy effectiveness analysis (as shown in the policy cycle Figure 11.2). Effective institutions are needed for designing, integrating and implementing successful environmental policy. There are several key challenges when conceiving of institutional effectiveness. One is to disentangle effectiveness from adjacent concepts such as compliance and enforcement (Chayes and Chayes 1993). This is important because an institution may see regular compliance from participants without being effective at all. Formal compliance with a regulatory instrument is an example of first-order effectiveness, addressing the identified problem but not necessarily addressing second- and third-order issues (other impacts and side effects).

If an institution relies on voluntary participation to solve an environmental problem (as is often the case internationally), then participants may be predisposed to comply with (or without) the institution because they are driven by the same reasons to join the institution in the first place. Thus, some institutions may not change behaviour so much as screen those that are not willing to comply in the first place (Downs, Rocke and Barsom 1996; Von Stein 2005; Simmons 2010). Alliances and clubs may provide opportunities for peer pressure to overcome institutional reluctance. Hybrid governance—i.e. combining different modes and instruments of governance—can help in mutual strengthening (e.g. information bases and regulatory approaches), as shown for the European chemical regulation REACH (Hey *et al.* 2007).

Another issue is to disentangle effectiveness from performance (Gutner and Thompson 2010). In relation to biodiversity, Le Prestre (2002) distinguishes between uses of effectiveness in problem-solving (see also Young 2011), goal attainment, implementation, compliance, behaviour change, cooperation and normative gains (justice).

Different approaches have been proposed to gauge institutional effectiveness, involving both qualitative and quantitative methods. For example, the Oslo-Potsdam solution (Hovi, Sprinz and Underdal 2003) proposes an analytical approach in which institutional effectiveness is measured against both a no-regime counterfactual (i.e. what would happen if there were no responsible institution) and an analytically derived collective optimum. The approach has been challenged—for example,

on the grounds of failing to propose a consistent baseline (Young 2003). A common alternative is an approach that relies on a well-specified statistical model to capture the no-regime counterfactual by offering an estimate of an ‘institutions effect’, controlling for other plausible effects on the behavioural variable of interest (Bernauer 1995).

### 11.4.2 Determinants of institutional effectiveness

What is important for strengthening existing international environmental institutions and/or creating new ones is the understanding of the effectiveness of these institutions (Young 2011). Increasingly important in international environmental policy discussions is the role of non-State actors such as local governments, cities and civil society organizations (Nasiritousi *et al.* 2016). In the absence of national government support for internationally agreed environmental goals, individual states and cities may carve out their own implementation agendas, such as in the Paris Agreement.

A major determinant of institutional effectiveness is the structure of the problem that the institution is trying to tackle (Mitchell and Keilbach 2001). These contextual factors include the distribution and enforcement problems faced, as well as various types of uncertainty (Koremenos, Lipson and Snidal 2001). It is also important that actors recognize that there is a problem (Mitchell 2009; Breitmeier, Underdal and Young 2011) and provide the necessary environmental leadership (Sprinz and Vahtoranta 1994).

Next are the specific actors involved in the policy problem. In some cases, the support of a powerful actor can be important for institutional success; however, this is not a necessary condition (Young 2011). Some institutions rely on a powerful coalition of willing actors to establish and run an effective institution (Sebenius 1991). These ‘pushers’ can be frustrated by ‘laggards’, however (Sprinz and Vahtoranta 1994; Haas, Keohane and Levy 1993). Often in complex negotiations, the lowest level of ambition that can be accepted by all becomes a significant barrier to progress (Underdal 1983).

One important mechanism for the efficacy of international institutions is domestic leverage. By providing the information resources, international institutions can induce change in national policies via domestic constituents that are empowered through that information provided by these resources (Dai 2005).

Another key determinant is institutional design. Young (2011) argues that design is often more significant than problem structure in determining an institution's effectiveness. The depth and density of regime rules is important (Breitmeier, Underdal and Young 2011). Moreover, the ‘deepest’ institutions do not necessarily scare off potential participants (Bernauer *et al.* 2013). Many actors are attracted to institutions that promise results (Hollway and Koskinen 2016).

However, the effects of an institution's design reach beyond what is strictly regulatory (Young 2011), especially where international organizations are established. An organization's design can foster certain institutional cultures and enable that organization to play a role in orchestrating various governance actors active in an issue area, such as private governance or public–private governance (Abbott and Snidal 2010; Andonova 2017).

Additional considerations of 'cutting-edge' concern, may hold significant interest for policymakers. These include: (i) the deep structure of international society in which environmental institutions are embedded, and the need to align the regime to this structure, most notably the power structure and norms; and (ii) the non-linear nature of human interactions with the environment (Young 2011).

#### 11.4.3 Vertical and horizontal interplay in multilevel governance

International environmental institutions interact among themselves and with institutions from other policy areas such as trade, energy and finance (Stokke 2001; Gehring and Oberthür 2008; Oberthür 2009; Oberthür and Stokke 2011). In general, MEAs support environmental decision-making at the national level; however, coherence and interaction remain a challenge. Institutional interaction may be distinguished in terms of horizontal (i.e. across agencies at the same level) and vertical (i.e. from international down to local government levels) interplay (Young 2002; Young 2006). It can also be distinguished in terms of functional interactions, when problems addressed by two or more institutions are linked in spatial, bio-geophysical or socio-economic terms. In this case, the operation of one institution directly influences the effectiveness of another (Adger, Brown and Tompkins 2005; Young 2002; Young 2006). Interplay can also be influenced by political linkages, when actors create links between institutions to advance individual or collective goals (Young 2002; Young 2006). It also opens options for forum shopping (i.e. trying to find an institutional arrangement that gives maximum benefit to an individual or collective) (Gehring and Oberthür 2009).

Interplay is likely to produce tensions between and among institutions. However, it is equally likely to result in positive or synergistic interaction. In case of tensions, these may be resolved through negotiation entailing compromises ensuring, however, that the institutions involved can operate without disproportionately affecting each other's ability to address the problems they were designed to address (Young 2011). The notion of interplay may provide relevant entry points to efforts aiming to improve horizontal and vertical integration.

As the 17 SDGs are intended to be fully integrated and universal, several countries are now grappling with the task of devising the most effective institutional arrangements to address the desired vertical and horizontal integration. The 2017 synthesis of the Voluntary National Reports submitted to date found that only about one third of countries were addressing all the SDGs (United Nations 2017), but almost all had put in place some relevant institutional arrangements.

Some examples of institutional approaches for horizontal integration include the following:

- ❖ Mongolia initially created a Ministry of Environment and Green Development, recently amended to Ministry of Environment and Tourism. The Ministry chairs a coordination committee for green development.
- ❖ Sri Lanka placed responsibility for the SDGs under the Office of the President, who chairs the National Council on Sustainable Development.

- ❖ Afghanistan has an existing High Council of Ministers which now supervises the nationalization of the SDGs and allocation of budgets against the targets and indicators.
- ❖ Costa Rica established a High-level SDG Council, jointly chaired by the President and three key ministers.
- ❖ Nigeria established a Presidential Committee on the SDGs and created the post of Senior Special Assistant to the President on the SDGs.
- ❖ Bangladesh formed an inter-ministerial SDG monitoring and implementation committee, involving 21 ministries.
- ❖ Belarus has a National Coordinator for the Achievement of the SDGs, chairing the National Council for Sustainable Development, comprising 30 agencies.
- ❖ Botswana has a National Steering Committee that includes the United Nations and all stakeholder groups.
- ❖ The Czech Republic has a Government Council for Sustainable Development, which includes nine thematic committees.
- ❖ Japan established the SDG Promotion Headquarters as a cabinet-level body headed by the Prime Minister.
- ❖ Denmark has an inter-ministerial SDG working group coordinated by the Ministry of Finance.

Examples of vertical integration include the following:

- ❖ Brazil's National Commission for the SDGs comprises 27 representatives from federal, state, district and municipal governments and civil society.
- ❖ Belgium's Inter-Ministerial Conference for Sustainable Development comprises federal, regional and community ministers responsible for sustainable development.
- ❖ India has created a National Institution for Transforming India, chaired by the Prime Minister.
- ❖ The Local Government Authority of the Maldives has aligned its five-year development plan, implemented by island councils, with the SDGs.
- ❖ Ethiopia has a Growth and Transformation Plan for implementation of the SDGs, with annual reports to a Standing Committee of Parliament.

Among others, Afghanistan, Argentina, Bangladesh, Belize, Benin, Botswana, Brazil, Chile, Costa Rica, the Czech Republic, Honduras, Kenya, Malaysia, Maldives, Nepal, Peru, Thailand and Zimbabwe have explicitly incorporated stakeholder engagement in their SDG institutional arrangements.

A pertinent question, given this wide range of institutional arrangements, is whether the lessons learned from previous attempts at institutional integration arrangements have been learned and incorporated into the current approaches. This should become more evident as more countries submit their Voluntary National Reviews to the High-level Political Forum on sustainable development.

An earlier form of horizontal integration, National Councils for Sustainable Development (NCSDs), came into vogue following the 1992 United Nations Conference on Environment and Development and were strengthened by the Johannesburg Summit on Sustainable Development in 2002. Their forms, functions and effectiveness vary considerably across countries (Osborn, Cornforth and Ullah 2014). Following some progress in implementation of the Johannesburg Plan

of Implementation, the 2012 United Nations Conference on Sustainable Development (Rio+20) launched the process that led to the SDGs (also called the post-2015 development agenda).

To feed into this process, the Global Network of National Councils for Sustainable Development and similar bodies reviewed 25 years of attempts at integration, to draw out good practice and success factors (Osborn, Cornforth and Ullah 2014). The Global Network and local governments responsible for Local Agenda 21 plans also illustrate the importance of vertical integration.

As with many Environment ministries, many NCSDs found it difficult to get their recommendations accepted, so they often resorted to disseminating key recommendations through non-traditional media channels. A sufficient arms-length relationship from the normal silo-like government bureaucracy may facilitate such non-traditional communication mechanisms and an ability to reach out to a wider group of stakeholders.

The composition of the NCSDs has usually reflected the national political context, and no clear preference has emerged. With only government agencies as members, there is a higher risk of being influenced by political interests and possibly create lower levels of ambition. Mixed memberships had difficulty in avoiding the dominance of government views and keeping track of the larger picture. Councils dominated by NGOs and other members outside government had difficulty in influencing decision-makers and often had long-term funding issues. A key factor in the success of NCSDs, however, has been the status and engagement of the Chair, with an independent Chair or co-Chair appearing to offer the best results.

Despite the drawbacks listed above, the following conclusion has emerged: "Where NCSDs exist, they should be nourished. Where they do not yet exist, careful consideration should be given to establishing them. Where they have been discontinued

for essentially short-term reasons, consideration should be given to re-establishing them, possibly in a new format" (Osborn, Cornforth and Ullah 2014).

## 11.5 Conclusions

The importance of good policy design cannot be overstressed. Some common elements are:

- i. setting a long-term vision and avoiding crisis-mode policy decisions, through inclusive, participatory design processes;
- ii. establishing a baseline, quantified targets and milestones;
- iii. conducting *ex ante* and *ex post* cost-benefit or cost-effectiveness analysis to ensure that public funds are being used most efficiently and effectively;
- iv. building in monitoring regimes during implementation, preferably involving affected stakeholders; and
- v. conducting post-intervention evaluation of the policy outcomes and impacts to close the loop for future policy design improvements (Mickwitz *et al.* 2009, p.12).

Focus also needs to be on ensuring that regulatory arrangements and policy instruments and tools take local conditions into account. The need for appropriate design applies also to international regimes (Young 2011). Policy design complexity increases when an effective mix of policies is required, often in areas under the control of different sectoral priorities. Policy coherence and environmental policy integration are critical considerations to ensure that policies are synergistic and do not undermine each other. Institutional effectiveness often springs from collaborative and participatory arrangements, involving both horizontal and vertical integration.

Policy diffusion is generally positive but can be misused if: (i) the policy adopted is not truly effective in the new context; and (ii) the transferability of the policy is merely assumed and not tested under different conditions. While it is human nature to want to copy, there is no substitute for evidence-based policy.

# Chapter 12

## Air Policy

© Yekbun Gurgoz

**Coordinating Lead Author:** Peter King (Institute for Global Environmental Strategies)

**Lead Authors:** Frederick Ato Armah (University of Cape Coast), Phillip Dickerson (United States Environmental Protection Agency), Cristina Guerreiro (Norwegian Institute for Air Research), Terry Keating (United States Environmental Protection Agency), Oswaldo dos Santos Lucon (São Paulo State Environment Secretariat, Brazil), Asami Miyazaki (Kumamoto Gakuen University), Amit Patel (Planned Systems International, Inc.), Stefan Reis (Centre for Ecology and Hydrology, Natural Environment Research Council),

**GEO Fellow:** Kari DePryck (Institut d'études politiques de Paris)

## Executive summary

**Institutional capacity to manage air pollution, climate change, stratospheric ozone depletion and persistent bio-accumulative toxic substances varies significantly across the world** (*well established*). In some regions and countries (e.g. North America, Western Europe, East Asia), there are well-developed federated systems of national, provincial and local policies and enforcement programmes. In other regions, international agreements or national legislation may exist, but implementation and enforcement are weak due to a lack of institutional capacity at the national or subnational scale (*established but incomplete*). In some regions, city governments are leading the way with benefits for other parts of their countries {5.5, 12.2}.

**Different investments are needed to improve management capacity in different regions.** For example, the GEO-6 regional assessments identified improving air quality monitoring infrastructure as a priority for Africa and Latin America and improving the use of benefit–cost analyses of climate change and air pollution mitigation measures as a priority for Asia and the Pacific {5.1}.

**Traditional regulatory approaches, including the use of emissions and technology standards, have been successful in addressing some pollution sources** (*established but incomplete*). Successes are evident in declining trends in emissions and increasing trends in economic activity and production. However, such approaches rely on adequate human resources and effective enforcement and legal systems, which may not exist {12.2.1, 12.2.2}.

**There is no single global agreement addressing air pollution, but there is a patchwork of regional intergovernmental agreements and initiatives focused on public–private partnerships** (*unresolved*). Global agreements have been adopted to address climate change, stratospheric O<sub>3</sub> depletion, persistent organic pollutants, and mercury {5.5, 12.2.5}.

**National commitments on climate change under the United Nations Framework Convention on Climate Change (UNFCCC) processes are still insufficient to meet the agreed global temperature stabilization goals, and options are foreclosing** (*established but incomplete*). The 2015 Paris Agreement on climate change set a limit to the average global temperature rise in this century well below 2 degrees Celsius, with the ambition to achieve 1.5 degrees or less, as a means of transiting towards a low-carbon and resilient future. To date, the set of national commitments and their implementation is not on track to avoid dangerous to catastrophic climate change, and delayed ambitions will lead to greater risks to the economy and to overall planetary health {5.5}.

## 12.1 Introduction

The composition of Earth's atmosphere is one of the major determinants of a healthy planet, influencing the climate, ecosystems and human health. This is highlighted by the existence of a direct or indirect link between the challenges of air pollution, climate change, stratospheric ozone depletion, persistent bioaccumulative and toxic (PBT) chemicals and each of the Sustainable Development Goals (SDGs) (United Nations 2015).

A plethora of international, national, subnational and regional policies have been deployed to address these challenges. The fundamental forms include:

- i. technology or emissions standards, commonly referred to as 'command and control';
- ii. planning regimes;
- iii. market interventions;
- iv. public information; and
- v. cooperative forums, including international agreements.

The various policy instruments that are used in each of these approaches are discussed in the following sections along with a case study to illustrate each approach. Key features of each case are highlighted using the methodology described in section 10.6. The case studies are selected from a diverse range of geographical contexts, spatial scales and implementation time frames. The case studies are not intended to be all encompassing, but highlight the context-specific nuances, generic patterns and issues that require attention from relevant stakeholders to elicit better policy outcomes. They are not intended to be replicable without considering the local context.

Policies enacted to address air pollution, climate change, stratospheric ozone depletion and PBTs should account for the mix of emissions, the atmospheric or environmental lifetime of the pollutant and its associated benefits and trade-offs (Melamed *et al.* 2016). Pertinent questions include:

- i. how can goals for affordable, clean and reliable energy across spatial scales (local, national, regional, global) be achieved by considering possible synergies and trade-offs?;
- ii. what synergies and co-benefits between climate policy and air pollution control can be identified?; and
- iii. how will emissions of greenhouse gases (GHGs) and air pollutants co-evolve in scenarios with and without policy interventions, such as context-specific regulation of PBTs, climate policy and air pollution control?

From a systems perspective, the existence of various policy instruments and regimes at a range of spatial and temporal scales brings into sharp focus the complexity of addressing air quality challenges in an integrated and comprehensive manner. This makes it imperative to take an integrated approach to address potential conflicts and define trade-offs between environmental policy objectives, as well as to isolate and consolidate policies with possible co-benefits such as improved energy security, urban air quality and human health (see Section 11.3).

## 12.2 Key policies and governance approaches

### 12.2.1 Planning regimes

Planning regimes (or frameworks) establish ambient targets (e.g. concentration standards, total pollutant loads or a change in global mean temperature) and emissions budgets (or ceilings). Clusters of policies are then developed and implemented to meet the targets or budgets. Progress towards these is monitored, and if necessary, additional policies are developed or existing policies are revised. Planning regimes are often considered to be fundamental to managing air pollution, climate change, ozone-depleting substances (ODSs) and PBTs, as they provide a strategic policy framework within which specific actions can be integrated.

Ambient concentration standards or other environmental targets define the desired state of the environment, often linked to cause–effect relationships in relation to human health. Emissions budgets, pollutant loads or ceilings are the estimated levels of pressure that still enable achievement of the desired state, or present a no-effect threshold (e.g. critical loads/levels). As an example, the US National Ambient Air Quality Standards (NAAQS) are standards for harmful pollutants established by the US Environmental Protection Agency (EPA) under authority of the Clean Air Act (42 U.S.C. 7,401 *et seq.*). These standards are applied for outdoor air throughout the country (United States Environmental Protection Agency 2016) and aim to protect human health from harmful air pollution.

Emissions budgets can be related to environmental targets using quantitative (e.g. atmospheric or climate) models properly evaluated against field observations. In the case of secondary pollutants (which are created in the atmosphere) or pollutants that have long lifetimes in the environment, the relationship between emissions and ambient concentrations may not be linear. Making a causal linkage between emissions

**Table 12.1: Typology of policy and governance approaches described in this chapter**

| Governance approach                | Policy instrument(s)                                                                                 | Case study                                                                          |
|------------------------------------|------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| Planning regimes                   | Ambient standards, emissions budgets                                                                 | United Kingdom of Great Britain and Northern Ireland Climate Act and carbon budgets |
| Technology and emissions standards | Emissions standards, fuel quality standards, efficiency standards, best available control technology | Diesel emissions standards in Europe                                                |
| Market interventions               | Subsidies, tax policy, tradeable credits/allowances                                                  | Improved cookstoves in Kenya (Global Alliance for Clean Cookstoves)                 |
| Public information                 | Information, forecasts, labelling and branding                                                       | Provision of real-time air quality data and forecasts                               |
| International cooperation          | Multilateral and bilateral binding agreements, voluntary organizations                               | ASEAN Agreement on Transboundary Haze                                               |

and the desired state is often important to justify the extent or costs of emissions controls or other policies and requires a significant amount of information (as inputs to the model) and expertise. However, in cases where emissions are high and the government's technical planning capacity is low, it is often not necessary to quantify the linkage between policies and the desired state to justify some control measures on the largest sources of emissions. It may be sufficient to qualitatively demonstrate that the sources contribute to adverse impacts and that there would be benefits from controls, with progress towards long-term objectives being achieved through implementation.

Linked to emissions budgets, emissions trading schemes have been introduced in particular for GHGs, where the location of emissions matters less in contrast to air pollutants. In December 2017, China launched its emissions trading system (United Nations Framework Convention on Climate Change [UNFCCC] 2017a), which will initially cover only the electricity sector. However, it is set to be the world's largest system of its sort and accounts for approximately 3 billion tons of traded CO<sub>2</sub>. A similar system is in place in Europe, with approximately 2 billion tons traded (European Commission 2018). Similar trading schemes exist in several countries and regions (Carbon Market Data 2018). By setting emissions budgets, which may gradually be constrained further, prices for traded emissions may be adjusted.

As noted in section 5.5, countries have identified different ambient concentration standards based on their own interpretation of the epidemiological evidence on relationships between environmental state and health effects; their existing levels of air pollution; and their own perceptions about their ability to achieve decreases in air pollution. The World Health Organization (WHO) has established guidelines and interim targets (WHO 2018) that countries can use to establish their own standards and targets. As WHO and individual countries establish or revise their ambient standards based on new information, other countries often take note of the changes and consider whether to make similar changes to their own standards. For the protection of sensitive habitats and ecosystems, critical loads and critical levels have been set in the context of the United Nations Economic Commission for Europe (UNECE) Convention on Long-range Transboundary Air Pollution (CLRTAP), initially focusing on acidification in the early 1980s, and later extended to include nutrient critical loads and ammonia (NH<sub>3</sub>) critical levels based on growing evidence of ecosystem damage and biodiversity losses even at lower concentration and deposition levels, stemming, for instance, from agricultural NH<sub>3</sub> emissions (Sutton, Reis and Baker eds. 2009).

Emissions budgets and ceilings not only provide a way of evaluating whether a suite of policies would be expected to achieve the relevant environmental targets; they also provide a way of apportioning responsibility for achieving environmental targets among regions, jurisdictions, sectors or individual sources. For example, emissions budgets have been applied at the national and state level in air pollution planning and at the national level in international agreements to mitigate ODS emissions. Within Europe and the UNECE region, the 1999 Gothenburg Protocol to Abate Acidification, Eutrophication and Ground-level Ozone (as amended) under CLRTAP (UNECE 2018) as well as the European Union (EU) National Emission

Ceilings Directive (European Environment Agency [EEA] 2016a) present recent examples of national emissions ceilings agreed for pollutants known to contribute to a range of environmental and human health effects.

In the following case study, emissions budgets are applied to long-lived GHG emissions in the United Kingdom.

#### **Case study: The United Kingdom of Great Britain and Northern Ireland's energy and climate policies**

The 2008 Climate Change Act (United Kingdom of Great Britain and Northern Ireland [UK] Government 2008a; UK Government 2008b) is an example of how a national policy can be established within an international framework to tackle climate change (including targets and timeframes, carbon prices and emissions trading). Legally binding targets aim to progressively reduce emissions through five-year carbon budgets up to 2050, with significant benefits such as international market competitiveness, resource conservation, cost-effective removal of barriers, support to low-carbon technologies, promotion of carbon capture and storage and considerations of social implications such as fuel poverty. To achieve such aims, practical measures included mandatory cap-and-trade schemes, standards, financing and taxing, innovation strategies and technology deployment (UK, Department of Trade and Industry 2007).

**Table 12.2: Summary of assessment criteria: United Kingdom of Great Britain and Northern Ireland's energy and climate policies**

| Criterion                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | References                                                                                                                                   |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Success or failure</b>         | GHG emissions reduced by 5 per cent/year since 2012, reaching 42 per cent below 1990 levels in 2016, with the economy growing by 60 per cent. Between 2008 and 2015 GHG per capita emissions fell from 8.22 to 5.99 tCO <sub>2</sub> , GHG per GDP (0.20 to 0.15 tCO <sub>2</sub> /2010 US\$, or 0.22 to 0.16 tCO <sub>2</sub> /2010 US\$ PPP); per capita energy use as total primary energy supply in tons of oil equivalent (TPES 3.37 to 2.78 toe/person), TPES per GDP (0.08 to 0.07 toe/1,000 2010 US\$) and electricity consumption per capita (6.01 to 5.08 MWh/person). | UK, Department for Business, Energy & Industrial Strategy 2016; International Energy Agency [IEA] 2017; UK, Committee on Climate Change 2017 |
| <b>Independence of evaluation</b> | Official Report to Parliament, supported by statistics.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                                                                                                                                              |
| <b>Key actors</b>                 | Mainly government bodies (including devolved administrations).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                                                                                                                              |
| <b>Baseline</b>                   | 1990 economy-wide GHG emissions, plus other associated baselines such as shares of renewable energy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                                                                                                                              |
| <b>Time frame</b>                 | GHG cuts of 80 per cent by 2050, with other interim targets (50 per cent by 2025), based on five-year carbon budgets, set 12 years in advance to allow preparation; other goals in the energy sector (renewable electricity and biofuels, transport efficiency, phase-in of electric vehicles, and others, including carbon capture and storage).                                                                                                                                                                                                                                |                                                                                                                                              |
| <b>Constraining factors</b>       | Slow GHG curbs in transport and buildings sectors, very limited carbon capture and storage.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                                                                                              |
| <b>Enabling factors</b>           | The main driver was a reduction in the use of coal by 75 per cent in the power sector. The Act had strong support due to lower energy bills, salience of scientific evidence, public awareness, political responses following innovation outside government, technology improvements, value of institutional innovation, use of evidence reframing climate change as an economic issue and the importance of leadership.                                                                                                                                                         |                                                                                                                                              |
| <b>Cost-effectiveness</b>         | Costs will be around 1–2 per cent of GDP in 2050, with significant business opportunities from a low-carbon economy (in 2009 a market worth GBP112 billion, with over 900,000 jobs).                                                                                                                                                                                                                                                                                                                                                                                             |                                                                                                                                              |
| <b>Equity</b>                     | Contraction and convergence approach.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                                                                                                                              |
| <b>Co-benefits</b>                | Improved market access, innovation, infrastructure resilience, energy supply security and system flexibility (storage, interconnection), take-up of new technologies, quality of life (air, water, health and well-being, land use).                                                                                                                                                                                                                                                                                                                                             |                                                                                                                                              |
| <b>Transboundary issues</b>       | Necessary policy realignment depending on exit from the EU and more ambition to fulfil the Paris Agreement goals.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                              |
| <b>Possible improvements</b>      | Scale-up low-carbon power generation, accelerated uptake of electric vehicles, more low-carbon heat alongside energy efficiency, restart work on carbon capture and storage, address land management practices, improve and clarify combinations of policy instruments (carbon pricing, standards and regulations, research and development funding, subsidies, market design and taxation).                                                                                                                                                                                     |                                                                                                                                              |

The Climate Change Act of the United Kingdom of Great Britain and Northern Ireland was the world's first legal instrument to set a long-range and significant carbon reduction target with a legally binding framework. Its approach considers a socio-technical transition and equity under a contraction and convergence model (Lovell, Bulkeley and Owens 2009; UK, Department for Business, Energy and Industrial Strategy 2016; Global Commons Institute 2018), with carbon budgets (caps in GHG emissions) used as an umbrella policy with strong direction for all the main economic sectors.

The importance of carbon budgets in guiding climate policies is illustrated by **Figure 12.1**, which allocates limits to cumulative emissions by country. A global carbon budget translates the

atmospheric carrying capacity to withstand anthropogenic GHG emissions within the goals set by the UNFCCC 2015 Paris Agreement (1.5–2°C), based on representative concentration pathways (RCPs). According to the Intergovernmental Panel on Climate Change [IPCC] (2014), for the period 2011–2100, limits range around 1,000 GtCO<sub>2</sub> (750–1,400 for 2°C with >66 per cent probability, or 550–600 Gt CO<sub>2</sub> for the 1.5°C goal with a >50 per cent chance).

Despite being an important lesson for other countries, the United Kingdom is still only partly on track to achieve its GHG emissions targets. The cluster of policies that have been implemented have been moderately successful in some sectors, such as transport and buildings. Entrenched interests,

Note: The regional allocation of cumulative CO<sub>2</sub> emissions following a linear emissions decrease to zero (left) and the RCP 2.6 global emission scenario (right). Per capita convergence occurs in 2035, and total cumulative emissions after 2013 are equal to 1,000 Gt CO<sub>2</sub>, for both scenarios. The side table compares regional cumulative emissions allocation (values in Gt CO<sub>2</sub> from 2014 onwards) from the RCP 2.6 scenario, for per capita convergence in 2035 and 2050 (Gignac and Matthews 2015).

such as coal-fired power plants and the transport sector, are not changing as quickly as needed to achieve the targets and additional policies to accelerate change will be needed to achieve the mandatory emissions cuts. Finally, since much of the country's existing environmental legislation arises from membership of the EU, a wide range of new policies and programmes would be needed after the British exit (UK, Committee on Climate Change 2017).

### 12.2.2 Technology and emissions standards

One of the most common approaches to address challenges related to air quality and climate change is to define emissions standards or other performance standards for specific industrial processes, equipment or products. Such standards may mandate that a process, piece of equipment or product should not emit more than a specified mass of emissions of a given pollutant per unit of time, input or output. For example, boilers used to generate electricity may be limited to a mass of emissions per kilowatt-hour generated; vehicles are typically limited to certain emissions per kilometre (km) travelled. Alternatively, a standard may require the application of a specific type of technology or a specific operational practice. For example, to limit emissions of fugitive dust from a construction site, vehicles leaving the site may be required to go through a wheel wash station. In most cases, standards are designed to be neutral with respect to the choice of fuel or to the choice of a control manufacturer, but the general principle is that the polluter is responsible for attaining the standard and hence should bear the cost of emissions control. For example, polluters are responsible for retrofitting existing technologies, where specific equipment needs to be installed to achieve existing or new emissions standards. Where emissions control technologies are integrated into new equipment—for example, in the case of vehicles that comply with Euro emissions standards, which must pass type approval at production—the costs of emissions control are included in the unit price.

The implementation and enforcement of technology and emissions standards present a direct measure affecting 'pressures' and contribute to the attainment of the emissions targets and budgets, the desired 'state' established in a planning regime (see Figure 1.2, Chapter 1). Often referred to as 'command and control' regulations, technology and emissions standards may be implemented and enforced through permit programmes, type approval schemes, inspections and audits, and reinforced by emissions monitoring and reporting requirements. Technology and emissions standards, however, may also be developed and applied voluntarily by industry groups, self-policed or subject to third-party verification, and associated with branding programmes (see section 12.2.4). Lifestyle choices and consumption patterns may play a vital role in determining the effectiveness of voluntary approaches.

Different standards in jurisdictions in the same geographical market increase the costs to manufacturers of products and equipment, which are required to meet the various standards. Although regulatory compliance costs are only one factor that affects business location decisions, a lack of harmonization of standards can lead to shifts in economic activity and associated emissions between jurisdictions as businesses seek locations with lower overall compliance costs. Therefore, standards are typically defined at the national level, taking into account standards in other countries, jurisdictions and markets.

Under the US Clean Air Act, New Source Performance Standards (NSPS) define a minimum level of air pollution control for all major new industrial emissions sources across the country, but more stringent standards may be applied depending on the level of existing pollution. To prevent the deterioration of air quality in areas already meeting the National Ambient Air Quality Standards (NAAQS) short-term exposure to air pollution, new major sources are required to use Best Available Control Technology (BACT), which is determined on a case-by-case basis as part of a permitting process and is at least as stringent as the NSPS. In polluted areas that already exceed the NAAQS, major new sources are required to meet the Lowest Achievable Emission Rate (LAER), which reflects the most stringent requirements in practice. Existing sources in such areas are required to meet the less stringent standard of Reasonably Available Control Technology (RACT). The USEPA maintains a database of these standards and case-by-case determinations in what is known as the RACT/BACT/LAER Clearinghouse (United States Environmental Protection Agency 2018b). As technology evolves, so do the RACT/BACT/LAER determinations, but by making the information public, the standards in different jurisdictions can evolve together. Likewise, the Industrial Emissions Directive (2010/75/EU) regulates industrial activities in Europe and also uses a legally binding concept of 'Best Available Techniques' (BAT) to set environmental performance levels which industry must achieve (European Commission 2018b). The definition of a BAT is done through a transparent exchange of information between industry, non-governmental organizations (NGOs) and regulators, and is recognized beyond the EU.

For marine shipping emissions, the International Maritime Organization (IMO) and the International Convention for the Prevention of Pollution from Ships (MARPOL, Annex VI) (International Maritime Organization [IMO] 2018) set standards for a global limit for sulphur in fuel oil used on board ships of 0.50 per cent m/m (mass by mass), to enter into force on 1 January 2020, representing a fuel-based standard. Compliance can be achieved by ships using low-sulphur compliant fuel oil. In contrast, a nitrogen oxide (NO<sub>x</sub>) Emission Control Area (NECA), which will enter into force for the North Sea and the Baltic Sea from 1 January 2021, will require all vessels built after 2021 to comply with emissions standards aimed to reduce NO<sub>x</sub> emissions by 80 per cent compared to present levels. Compliance can only be achieved in practice by equipping vessels with catalysts or using liquefied natural gas (LNG) fuels. Existing emission control areas for sulphur oxide (SO<sub>x</sub>) cover the Baltic Sea (19 May 2006) and the North Sea (22 November 2007), and for SO<sub>x</sub> and NO<sub>x</sub> the North American east and west coasts (1 August 2012) and the US Caribbean Sea (1 January 2014).

The effectiveness of technology and emissions standards depends on the level of compliance, affordability and the extent to which the standards reflect the real-world impact of the emissions sources. The level of compliance, in turn, depends on the level of education, as well as monitoring and enforcement, among other factors. However, in countries or jurisdictions where the government has little capacity to enforce standards through inspections and audits, compliance with standards can be low. Even in countries where sophisticated inspections and audits are routine, some businesses and individuals may violate standards to gain a competitive economic advantage.

Cost-benefit analyses, such as that conducted by Åström *et al.* (2018), can provide an insight into the cost-effectiveness and the distributional effects of setting standards, for both *ex ante* and *ex post* evaluations.

Finally, the use of solid fuels, including biomass, in residential boilers is gaining more attention recently, as other key sectors have been regulated in the past decades. For example, the European Commission has established performance standards for solid-fuel space heaters with a nominal heat output of 50 kW or less, which have so far been mostly unregulated and may contribute to local air quality problems due to emissions of NO<sub>x</sub> and particulate matter less than 2.5 µm (PM<sub>2.5</sub>) (European Union 2015). Similarly, the EU Ecodesign-Directive (Directive 2009/125/EC) establishes a framework for setting ecodesign requirements for energy-related products, household appliances, and information and communications technologies.

The following case study illustrates the effectiveness of emissions standards through a type approval scheme through the example of the Euro 6 vehicle emissions standards, the difference between how compliance is measured and

real-world performance, and the efforts of some businesses to thwart compliance testing.

### Case study: Excess diesel emissions in Europe

Since the 1970s, the key mechanism for regulating vehicle air pollutant emissions in Europe has been a regulatory/command and control policy that has progressively set increasingly stringent standards for emissions of air pollutants and GHGs (since 2009). A series of directives, known as Euro standards, define the acceptable limits for exhaust emissions of new road vehicles sold in the EU. The Euro standards, starting with the release of Euro 1, which entered into force in 1993, have since been amended regularly. The most recent Euro standard is Euro 6 for light passenger and commercial vehicles, which came into force in 2014 (Commission Regulation (EU) No 582/2011).

The aim of this policy is to contribute to reductions in actual or real-world emissions from road transport, an important source of GHG and air pollutant emissions. However, road transport enables people to access employment, education, goods and services. Manufacturers of road vehicles in the EU also contribute to the economy and employment. Hence, the policy aims to achieve a balance across these objectives.

**Table 12.3: Summary of assessment criteria: Excess diesel emissions in Europe**

| Criterion                         | Assessment                                                                                                                                                                                                                                                                                                                                            | Reference                                                                  |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| <b>Success or failure</b>         | The Euro standards have been successful in decreasing emissions of air pollutants and GHGs per unit of travel and decreasing measurable air pollution concentrations, especially close to roads. However, real-world reductions fall short of the potential reductions measured in laboratory testing.                                                | EEA 2015; EEA 2016a; EEA 2016b; EEA 2017                                   |
| <b>Independence of evaluation</b> | Independent evaluations of overall progress have been conducted.                                                                                                                                                                                                                                                                                      |                                                                            |
| <b>Key actors</b>                 | Associations of car owners and vehicles manufacturers, NGOs etc. were highly involved. It was a long process with a high level of stakeholder involvement.                                                                                                                                                                                            |                                                                            |
| <b>Baseline</b>                   | Quantitative baselines were established and updated with each amendment.                                                                                                                                                                                                                                                                              |                                                                            |
| <b>Timeframe</b>                  | Policies were implemented on time, but some intended targets were missed because of the inadequacy of the test cycle and wide-ranging exceptions enabling manufacturers to switch off emissions control technologies under certain ambient conditions.                                                                                                |                                                                            |
| <b>Constraining factors</b>       | Lobbying from industry has led to delays and weakening of the policy. In some cases, manufacturers have circumvented the standards designing cars to have lower emissions during testing than on the road.                                                                                                                                            | Grice <i>et al.</i> 2009; Guerreiro <i>et al.</i> 2010, p. 3; Hotten 2015; |
| <b>Enabling factors</b>           | The European regulatory and governance structure was key to enabling policy implementation. Some countries lacked the resources to independently verify emissions reported by manufacturers. The level of participation in policy development was high, leading to high levels of public approval.                                                    |                                                                            |
| <b>Cost-effectiveness</b>         | Costs and benefits, including impacts on health, agriculture and ecosystems, are considered carefully in the process of European policy development, aiming at high cost-effectiveness.                                                                                                                                                               | European Commission 2018                                                   |
| <b>Equity</b>                     | The impacts can be considered positive for everyone, but they particularly benefit people living close to roads, who may be economically disadvantaged.                                                                                                                                                                                               |                                                                            |
| <b>Co-benefits</b>                | The Euro standards set an example for the world. Industry is driven to innovate. Fuel efficiency increased, improving energy security and decreasing GHG emissions. Some national policies providing incentives to purchase diesel vehicles led to increases in NO <sub>2</sub> emissions. Transport subsidies may offset the reduction of emissions. | Franco <i>et al.</i> 2014; European Commission 2015; EEA 2015              |
| <b>Transboundary effects</b>      | As the Euro standards progressively penetrated the international second-hand vehicle market, vehicle emissions were lowered in countries without similar regulations.                                                                                                                                                                                 |                                                                            |
| <b>Possible improvements</b>      | Reduce the margins of technical uncertainty in testing, eliminate test flexibilities, and increase emissions checks of cars in circulation.                                                                                                                                                                                                           |                                                                            |

The main objective of the original European standards was the reduction of emissions of NO<sub>x</sub>, carbon monoxide (CO), PM<sub>2.5</sub> and volatile organic compounds (VOCs), as well as carbon dioxide (CO<sub>2</sub>) and other pollutants, and subsequent amendments have implemented further limits. Furthermore, increasingly strict Euro standards require cleaner petrol and diesel fuels (the quality of which was regulated by Directive 2003/17/EC, e.g. low sulphur content), leading to, for example, lower PM emissions. These regulations have been driven primarily by air pollution effects on human health and—to a lesser extent—natural and semi-natural ecosystems, in addition to climate change. These increasingly stringent emissions standards have achieved positive results. They have led to the introduction of new vehicle technologies, which have achieved significant reductions in vehicle emissions over recent decades in Europe. For example, the latest standard (Euro 6) for diesel cars requires a reduction of almost 97 per cent of PM emissions compared to the Euro 1 standard for a 20-year-old vehicle.

The Euro standards have been successful in decreasing emissions of air pollutants and GHGs per unit of travel, as well as reducing overall transportation emissions even while transportation activity has increased (EEA 2015, pp. 25, 30, 32, 33, 37, 38, 46; EEA 2017, p. 19). They have also led to a measurable decrease in air pollution concentrations, especially close to roads (EEA 2016b, pp. 31, 43, 77–79, 82). However, these reductions fall short of the targets outlined in the policy, due to differences between real-world behaviour and emissions under laboratory testing conditions (EEA 2015, p. 46; EEA 2016a, pp. 27–37). These differences have increased considerably since 2000, especially for CO<sub>2</sub> and NO<sub>x</sub> emissions in diesel cars, mainly due to:

- i. the test procedure, which did not reflect real-world driving conditions;
- ii. flexibilities in the procedures, which allowed manufacturers to achieve lower fuel consumption and emissions values during testing;
- iii. several in-use factors, such as driving style and environmental conditions; and
- iv. the use of 'defeat devices' designed to lower emissions measured during vehicle testing in the laboratory but not on the road.

Only after the diesel-gate scandal in 2015 (Hotten 2015) was there enough political awareness and will to change the laboratory test cycle to better reflect real-world emissions (European Union 2016).

In view of the shortcomings of the implemented standards, the test cycles were reviewed, and new and more reliable emissions tests in real driving conditions, as well as improved laboratory tests, were introduced for new car models sold in Europe in 2017. In addition, the European Commission presented a new proposal in 2018, aiming to reduce the margins of technical uncertainty in testing, eliminate test flexibilities and increase emissions checks of cars in circulation.

### 12.2.3 Market interventions

As a potential alternative to mandating lifestyle and technology choices, governments can also guide lifestyle and choices by creating economic incentives (e.g. subsidies, tax credits,

loans or price guarantees) or disincentives (e.g. fees or taxes) in existing markets or by creating new markets for rights or commodities that have not been traded (e.g. emissions reduction credits or renewable energy credits). All these types of market interventions have been used to some extent to mitigate air pollution, climate change, ODSs or PBTs.

In the DPSIR framework (Figure 1.2, Chapter 1), market interventions affect the 'drivers' of environmental issues, which in turn affect the 'pressures' and the environmental 'state'.

Although market interventions do not directly decrease emissions or ambient concentrations, they provide regulated individuals and businesses with flexibility and can create an incentive to improve performance and lower costs. Thus, a properly designed and adjusted market intervention may achieve emissions reductions more efficiently than 'command and control' approaches.

Markets are affected by many factors which are beyond government control. Therefore, market interventions must be adjusted periodically to reflect changing conditions. It is helpful if those adjustments can be made within the context of a planning regime (see section 11.3) so that progress towards a desired state can be evaluated and tracked.

In some cases, government interventions are needed to bring new technologies to a given market. Once the technology is introduced to the market and provided with a foothold, such as through initial subsidies or loans, it should be able to compete with other technologies without government assistance. The following case study explores how the Government of Kenya helped introduce clean cookstoves and fuels to reduce residential air pollution.

#### **Case study: Improved cookstoves in Kenya**

Household air pollution from the use of traditional fuel sources (wood, dung and charcoal) for cooking is a leading contributory factor to the global burden of disease (Lim *et al.* 2012; Cepeda *et al.* 2017; Landrigan 2017, see Section 5.2.4). A range of chronic illnesses such as cataracts, lung cancer and bronchitis are associated with smoke from cooking, with women and children most affected (Cepeda *et al.* 2017). Beyond this, black carbon (a household air pollutant) has been identified as the second most important anthropogenic emission that significantly affects the world's climate (Bond *et al.* 2013; Myhre *et al.* 2013).

The adverse effects of the dependence of the developing world on traditional renewable energy for cooking has necessitated the timely intervention by the Global Alliance for Clean Cookstoves (the Alliance), a public–private partnership geared towards the creation of a global market for improved, clean and efficient household cooking solutions in a bid to reduce the carbon footprint of highly polluting traditional stoves. The Alliance was launched in 2010 with an ambitious 10-year goal to foster the adoption of clean cookstoves and fuels in 100 million households by 2020. It partnered with NGOs, foundations, women's cooperatives, trade associations, academic institutions, investors and entrepreneurs to expand markets for clean cookstoves. Given the extensive use of unprocessed fuelwood in rural sub-Saharan Africa in particular, the Alliance is operational in a number of countries in this region, including Kenya, where 84 per cent of the population

use solid fuel for cooking and 16,500 deaths annually have been attributed to exposure to indoor air pollutants (Global Alliance for Clean Cookstoves 2012a).

Kenya's development, marketing and distribution of clean cookstoves is the most advanced in the sub-Saharan African region, having emerged in the 1980s led by development of the Kenyan Ceramic Jiko (United States Agency for International Development and Winrock International 2011). Yet by 2007, the penetration rate in the Kenyan market for cookstoves was approximately 36 per cent, and adoption in rural areas was quite low. Since then the Alliance has made notable inroads in the Kenyan cookstoves market through its partnership with the Clean Cookstoves Association of Kenya (CCAK) to encourage government officials to adopt market incentives—for example, abolishing or minimizing taxes and tariffs that impede the growth of the clean cooking sector. A notable accomplishment was the reduction in the import duty on efficient cookstoves from 25 per cent to 10 per cent by the Kenyan Government in 2016. The Alliance has also provided grants to boost brand-

building and marketing efforts and has supported two women-owned businesses through its Women's Empowerment Fund.

Carbon financing for clean cookstoves has not only been beneficial to Kenyans but has also enabled international companies to achieve their emissions reduction goals through carbon trading, which allows for carbon credits to be used to comply with emissions reduction obligations under cap-and-trade schemes or for voluntary reduction schemes (Lambe *et al.* 2015).

An evaluation of six types of biomass stove highlighted the need to address key factors that contribute to reducing emissions—namely: the cookstove design and performance; other potential sources of emissions; the availability and cost of cookstoves; ventilation; and the strategies to ensure the adoption and use of clean cookstoves (Pilishvili *et al.* 2016). The results of the evaluation showed that the biomass stoves did reduce emissions compared with the three-stone traditional stove baseline. However, the reduction in emissions did not reach thresholds where public health benefits could be maximized.

**Table 12.4: Summary of assessment criteria: Improved cookstoves in Kenya**

| Criterion                         | Description                                                                                                                                                                                                                                                                                                                                                                                    | Reference                                                                                                                              |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Success or failure</b>         | Approximately 37 per cent (3.5 million) households use improved biomass cookstoves (ICSs), while over 50 per cent (approximately 5 million) households still use traditional biomass cookstoves. Between 240,000 and 300,000 ICSs are sold to new customers annually. The Kenyan Government aims to achieve 50 per cent of abatement potential (i.e. approx. 2.6 MtCO <sub>2</sub> e) by 2030. | Kenya, Ministry of Energy and Petroleum and Sustainable Energy for All 2016; Kenya, Ministry of Environment and Natural Resources 2017 |
| <b>Independence of evaluation</b> | Green Climate Fund, a UNFCCC funding mechanism.                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                        |
| <b>Key actors</b>                 | Over 80 per cent of the market share for biomass ICSs is dominated by artisanal fabricated stoves.                                                                                                                                                                                                                                                                                             | Green Climate Fund 2018                                                                                                                |
| <b>Baseline</b>                   | The project started in 2010, and by April 2016 the Global Alliance for Clean Cookstoves project had sold approximately 251,000 cookstoves across Kenya.                                                                                                                                                                                                                                        | Natural Capital Partners 2018                                                                                                          |
| <b>Timeframe</b>                  | GHG emissions mitigation objective of 30 per cent by 2030 in relation to the business-as-usual (BAU) scenario of 143 MtCO <sub>2</sub> e. Of this, ICS interventions are considered to have an abatement potential in 2030 of 5.6 Mt CO <sub>2</sub> e.                                                                                                                                        | Global Alliance for Clean Cookstoves 2014; Green Climate Fund 2018                                                                     |
| <b>Constraining factors</b>       | Underdeveloped ICS supply chain; communities that collect wood for free; costs and risks associated with investment to cover remote rural areas; weak consumer awareness; regulatory constraints (i.e. import duties, taxes and poorly targeted subsidies); limited product testing capacity to enforce standards; and insufficient investment into product improvement.                       | Global Alliance for Clean Cookstoves 2012b; Green Climate Fund 2018                                                                    |
| <b>Enabling factors</b>           | Kenya removed the 16 per cent value added tax (VAT) on LPG, reduced the import duty on efficient cookstoves from 25 per cent to 10 per cent, and placed a zero-rating VAT on improved cookstoves, raw materials and their accessories.                                                                                                                                                         | Global Alliance for Clean Cookstoves 2016                                                                                              |
| <b>Cost-effectiveness</b>         | Design of cookstoves does not offer the full benefit of fuel savings and reduced emissions and high quality cookstoves are not easily distinguished from their competitors.                                                                                                                                                                                                                    |                                                                                                                                        |
| <b>Equity</b>                     | Households in the poorest quintile, women in younger age groups and people living in remote areas are less likely to adopt and install improved cookstoves.                                                                                                                                                                                                                                    | Silk <i>et al.</i> 2012; Kapfudzaruwa, Fay and Hart 2017                                                                               |
| <b>Co-benefits</b>                | Livelihood improvements, social impacts (including gender), reductions in co-pollutants (ozone damage to crops), among others.                                                                                                                                                                                                                                                                 |                                                                                                                                        |
| <b>Transboundary effects</b>      | Lessons learned can be applied to other sub-Saharan African countries.                                                                                                                                                                                                                                                                                                                         |                                                                                                                                        |
| <b>Possible improvements</b>      | Customer segmentation studies are needed to understand customer needs and tailor financial products for purchasers. Existing non-cookstove distribution and wholesale networks need to be used to improve consumer access and affordability.                                                                                                                                                   | (Global Alliance for Clean Cookstoves 2013; Kenya, Ministry of Energy and Petroleum 2015)                                              |

Overall the clean cookstove market in Kenya shows promise, but there is a strong need for policy intervention in rural areas to scale up the adoption and use of cookstoves. Human health could be better integrated within this policy in the future by clearly delineating the health indicators of local and global significance that need to be monitored periodically to effectively track progress in health benefits spatially and temporally.

#### 12.2.4 Information policies

In addition to using regulatory mandates and market incentives, governments can, at times, aim to support a change in lifestyle to either reduce emissions or exposure to harmful levels of air pollution by providing the public with better information. This goes in line with an improved understanding of the hazards and risks of exposure to air pollution in recent years (Kelly and Fussel 2015), although the importance of public education for air pollution control was raised more than 50 years ago by Auerbach and Flieger (1967). One example of such an approach is the provision of near real-time air quality observations and forecasts. The posting of near real-time air quality data online is increasingly common in many nations and major cities around the world. Some locations also provide air quality forecasts, predicting air quality levels for one or more days into the future. This information is often further circulated via other websites, social media, smart phone apps, newspapers, local radio and television. These dynamic media may be complemented by educational posters and pamphlets. The objective of providing such information is to encourage citizens to change their lifestyle to:

- decrease their exposure to pollution and, consequently, lower the risk of adverse health effects (e.g. by avoiding exercise outdoors during peak concentrations, or for especially vulnerable individuals to stay indoors); and
- decrease their emissions (e.g. commute via public transportation instead of personal transport or curtail use of wood fires or other biomass burning during forecast pollution episodes).

Air quality forecasts and real-time values may be used to complement other air pollution control policies. For example, some localities in the United States impose wood-burning restrictions when a pollution episode alert has been issued, while in Europe several large cities, such as Paris, have issued restrictions for private car use during high pollutant concentration episodes in recent years. For the severest of episodes, governments may shutdown factories and other non-essential activities. In China, several cities impose a ban on trucks and other high emission vehicles during the day to manage air quality.

Other examples of providing information to guide behaviour are labelling and branding. In this context, labelling refers to providing information on a product about its environmental impacts, such as its relative emissions or energy consumption, to inform consumers' choices. Such labels may be required by government regulations (e.g. emissions and fuel economy estimates are required on the labels for new cars in the United States) or may be voluntarily provided by the manufacturer. Branding, in this context, involves associating a logo or symbol with a product or service that indicates to consumers that the

product or service has met some set criteria for environmental performance (e.g. Energy Star). Such brands have been established by governments, industry associations or public advocacy groups as voluntary programmes, and often involve independent testing.

These approaches need to reach a threshold level of awareness and recognition across their target populations before they can have much effect on environmental pressures (consumption and other emissions-generating behaviour) and impacts (exposure-related behaviour). However, once the threshold is reached, citizens and consumers may begin to expect and demand such information. Moreover, increasing awareness of the sources and impacts of pollution may increase public demand for cleaner air, lower emitting products and services, and more stringent policies.

Access to information also promotes innovation. In the past, most of the information on ambient air quality originated from regulatory bodies. With the curiosity of the public to know more about the ambient air quality and its linkages to human health, there is now a new market of non-regulatory air quality monitors, which are providing the same information as the regulatory monitors at lower cost. While the data quality produced by (often referred to as low-cost) air quality sensors for crowdsourcing of air quality information is at times questionable (Lewis and Edwards 2016; Thompson 2016), the empowerment of citizens to take ownership of environmental data should not be underestimated (see Section 25.2). This serves society with information and lets the public make informed decisions on when to go out, when to spend more time outdoors etc., and is further supported by activities to make air quality information openly available and easily accessible—for instance, through the OpenAQ initiative (<https://openaq.org>), which aims to “enable previously impossible science, impact policy and empower the public to fight air pollution through open data, open-source tools, and cooperation”.

The need for more information has led to the establishment of private organizations as well as regulatory agencies taking charge of experimenting with novel ways to generate information most suitable for consumption. Experimentation is feasible to expand, and there is room for the regulatory bodies to step in and endorse the emerging technologies for further expansion.

With the wide use of smart phones and open applications, this information is now serving everyone with access to a phone, in addition to traditional dissemination channels. Due to the wide spread use of mobile applications, citizens' awareness of and access to information is increasing rapidly. As a consequence, the public has generated a demand for change. The availability of targeted information can further empower individuals to be prepared and manage health risks in response to environmental hazards, illustrated, for example, by the Know and Respond information system in Scotland, or the United Kingdom of Great Britain and Northern Ireland-wide air pollution forecast provided by the UK, Department for Environment, Food and Rural Affairs (2018). Know and Respond is a free service to subscribers in Scotland that sends registered users an alert message if air pollution in their area is forecast to be moderate, high or very high (Air Quality in Scotland 2018).

### Case study: AirNow, real-time air quality data and forecasts

In 1995, the American Lung Association of Maryland, a non-governmental advocacy group, began to create a daily map of ozone observations from the monitors operated by the State of Maryland (state and local governments are responsible for operating air quality monitoring stations in the United States). In 1997, the daily ozone maps were expanded to 14 north-eastern states. In 1998, the USEPA took over the operation of the central data system, added seven more states and named the system AirNow (<http://airnow.gov/>).

Over the next 10 years, AirNow grew as more states and local agencies contributed their data. By 2008, agencies in all 50 US states, 4 Canadian provinces and the national government, and 2 Mexican states were submitting data. Over time, the data system and product delivery were improved incrementally, experimenting with new products and services. In 2009, the system architecture and software tools were overhauled to allow the software to be implemented in different settings. The new software, branded AirNow-International, was deployed in Shanghai, China, for the 2010 World Expo, and in Monterrey, Mexico in 2012.

AirNow currently gathers and distributes observations and forecasts from more than 130 federal, state and local agencies.

Data for the United States is provided to the public and the media using the Air Quality Index (AQI), a colour-coded and numerical scale based on the US National Ambient Air Quality Standards. An applications programming interface (API) has opened the data system to smart phone applications, which have proliferated. AirNow-International has increased its scope geographically, and the US Department of State has begun providing air quality observations from selected US embassies and consulates around the world.

As an information policy, the US EPA AirNow programme provides a low-cost but high-benefit example. By building on existing structures, such as monitoring networks and state or local air quality agencies, the programme leverages infrastructure in a new way. The primary benefit of this information policy comes by helping individuals reduce or avoid exposure to high levels of pollution. Timely information encourages citizens to take mitigative actions to reduce their contributions to pollution. In addition, the provision of information creates an awareness of air pollution, a demand for cleaner air and greater acceptance of other regulatory and market policies to decrease pollution. While no formal evaluation of the programme exists, various studies show that air quality information has an impact on awareness and lifestyle.

**Table 12.5: Summary of assessment criteria: AirNow, real-time air quality data and forecasts**

| Criterion                  | Assessment                                                                                                                                                                                                                                                                                                                                                                             | Reference                                                                                                                                                                                                                                                                                          |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Success or failure         | Studies have demonstrated increased awareness due to alerts, but changes in lifestyle (e.g. decreased driving, energy consumption) are more difficult to quantify.                                                                                                                                                                                                                     | Blanken, Dillon and Wismann 2001; Henry and Gordon 2003; Mansfield and Corey 2003; Kansas Department of Health and Environment 2006; Mansfield, Johnson and von Houtven 2006; McDermott, Srivastava and Croskell 2006; Semenza <i>et al.</i> 2008; Mansfield, Sinha and Henrion 2009; Neidell 2008 |
| Independence of evaluation | Various studies.                                                                                                                                                                                                                                                                                                                                                                       |                                                                                                                                                                                                                                                                                                    |
| Key actors                 | National, state/provincial and local governments.                                                                                                                                                                                                                                                                                                                                      |                                                                                                                                                                                                                                                                                                    |
| Baseline                   | Depends on the location.                                                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                                    |
| Timeframe                  | Between 1995 and 2008, the system evolved from an effort by one state to a system involving agencies in all 50 US states, 4 Canadian provinces and the national government, and 2 Mexican states. Currently, more than 130 federal, state and local agencies are participating.                                                                                                        |                                                                                                                                                                                                                                                                                                    |
| Constraining factors       | Air quality information can generate anxiety about potential health effects and may encourage some people to seek unnecessary medical attention. Moreover, once information is made freely available, a variety of uses may be devised that were not envisioned when the system was created. Policies and attitudes about data transparency and openness can be important constraints. |                                                                                                                                                                                                                                                                                                    |
| Enabling factors           | A prerequisite is an effective air quality monitoring infrastructure and data collection and dissemination programme.                                                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                    |
| Cost-effectiveness         | Additional costs of the data management and dissemination are small compared to the costs of the monitoring activity and the value of the media coverage.                                                                                                                                                                                                                              |                                                                                                                                                                                                                                                                                                    |
| Equity                     | Access to air quality information is not uniform. People who are poorly educated or without access to the Internet may be excluded.                                                                                                                                                                                                                                                    |                                                                                                                                                                                                                                                                                                    |
| Co-benefits                | Creates a greater demand for air quality and improves acceptance of air quality management policies.                                                                                                                                                                                                                                                                                   |                                                                                                                                                                                                                                                                                                    |
| Transboundary effects      | The programme is expanding internationally under the auspices of the Group on Earth Observations.                                                                                                                                                                                                                                                                                      |                                                                                                                                                                                                                                                                                                    |
| Possible improvements      | As access to various types of information increases, expectations for access to air quality information also rise.                                                                                                                                                                                                                                                                     |                                                                                                                                                                                                                                                                                                    |

## 12.2.5 International cooperation

No one can live without air, and its quality is indispensable. However, 90 per cent of the global population is now forced to live with unhealthy air, particularly in Asia and Africa (WHO 2018). Air pollution and PBTs are of particular concern, as they travel locally, internationally, regionally and globally. International cooperation plays an important role when air pollution crosses borders or needs to be addressed across borders.

International cooperation can take many forms, ranging from formal to informal, bilateral to multilateral diplomacy. Governments are one of the key actors to align their actions—negotiating and concluding multilateral environmental agreements (MEAs) in a tangled web of national interests, providing international aid, conducting capacity-building/technical assistance under or beyond the agreement, monitoring and modelling air pollution to improve scientific knowledge with help from a community of experts, sharing information with the public, raising awareness and engaging in voluntary efforts for further cooperation to reduce air pollution. Formal training, technology demonstration, and cooperative research and assessment activities provide more effective knowledge-sharing and capacity-building opportunities. These activities may have the most significant long-term influence on environmental outcomes, but their immediate impact is difficult to quantify. Local governments are important actors to implement national environmental policies. Cooperation from business and industry is crucial to increase the effectiveness of the policies. Considerable progress on policy cooperation, emissions control and reporting, and ecosystem recovery has been achieved under the eight legally binding CLRTAP Protocols. The application of the effects-oriented critical load concept with regional cost minimization of science-based mitigation measures, technical as well as structural, has offered a sophisticated but successful way forward for participating countries.

A relatively recent approach to international cooperation on air-related issues has been the development of public–private initiatives, such as the Partnership for Clean Fuels and Vehicles, the Global Alliance for Clean Cookstoves (see Section 12.2.3), the Global Research Alliance on Agricultural Greenhouse Gases, and the Climate and Clean Air Coalition for the Reduction of Short-Lived Climate Pollutants (CCAC). These initiatives bring together interested national governments, intergovernmental organizations, private-sector companies, civil society organizations and philanthropic foundations to advance specific pollution mitigation efforts. For example, CCAC was founded in 2012 by the United Nations Environment Programme (UNEP) and the governments of Bangladesh, Canada, Ghana, Mexico, Sweden and the United States, to catalyse action to decrease emissions of black carbon, methane and hydrofluorocarbons. CCAC now has more than 100 state and non-state partner organizations participating in 11 different initiatives. This could contribute to cleaner fuels and technologies in the homes of 3 billion vulnerable people suffering from household air pollution (Apte and Salvi *et al.* 2016).

International financial institutions such as the World Bank, the Asian Development Bank, the African Development Bank, the Global Environmental Facility and the Green Climate Fund play major roles in project funding. Financial assistance and cooperative implementation of control measures can have a clear and demonstrable effect on decreasing emissions in the short term, but the long-term impacts may be much larger if the control measures are replicated.

Regional organizations can function in two ways. One, like the EU, is taking the leading role in negotiations as a global actor and an increasing role in environmental politics, while the other, like the Association of South East Asian Nations (ASEAN), is to function as an international forum. Both provide opportunities to set regional agendas, learn new knowledge and perspectives, share information and discuss common issues. Treaty secretariats could influence the negotiation process among States under the accords. Like-minded groups, alliances and friends of the Chairs could also lead, mediate or slow down negotiations. Some of these cooperation processes could also be activated by environmental NGOs, green parties and citizens as well as international organizations such as WHO, the World Meteorological Organization (WMO), the Organisation for Economic Co-operation and Development (OECD), the International Energy Agency (IEA), the International Maritime Organization (IMO), the International Civil Aviation Organization (ICAO) and UNEP, helping to set the environmental agenda, framing environmental issues or providing resources for international cooperation.

As introduced in Section 5.5, global MEAs which have linkages to air pollution are those targeting climate change (UNFCCC), stratospheric ozone depletion (Vienna Convention and Montreal Protocol), mercury (Minamata Convention) and persistent organic pollutants (Stockholm Convention). Although there is no global convention on air pollution, several regional MEAs and bilateral agreements exist. One of the oldest regional MEAs is the 1979 CLRTAP negotiated under UNECE. Considerable progress on policy cooperation, monitoring and modelling, emissions control and reporting, and ecosystems recovery has been achieved under the eight legally binding CLRTAP Protocols.

It is difficult to evaluate the impact of international agreements. Compliance with legal commitments can be evaluated, but it is not always clear that emission decreases that occur are a result of an international agreement or if they would have occurred in the absence of the agreement. Furthermore, perfect compliance may be an indication of unambitious targets that require little more than business as usual efforts.

None of the MEAs identified above have an effective international enforcement mechanism. Depending on a country's own laws, a national government may be taken to court in its own country for not abiding by its international treaties. However, this kind of action is rare, and ensuring compliance with international commitments mostly relies on diplomatic or peer pressure.

The following case study explores the progress made under the regional agreement on transboundary haze negotiated under ASEAN in 2002. This case provides valuable lessons on the challenges of international cooperation.

### Case study: ASEAN Agreement on Transboundary Haze Pollution

Haze or smoke-haze as used in Southeast Asia is synonymous with air pollution from land and forest fires and agriculture-waste burning from rural populations. Transboundary haze pollution refers to haze pollution whose physical origin is situation wholly or in part within an area under the national jurisdiction of one country and which is transported into

the area under the jurisdiction of another country (ASEAN Agreement on Transboundary Haze Pollution). The worst haze episodes occur in years affected simultaneously by the climatological anomalies of *El Niño*—Southern Oscillation and Indian Ocean Dipole. The most recent severe haze event in 2015 was caused in part by the dryness triggered by both anomalies in the region, particularly on the Indonesian islands of Sumatra and Kalimantan (Kopplitz *et al.* 2016).

**Table 12.6: Summary of assessment criteria: ASEAN Agreement on Transboundary Haze Pollution**

| Criterion                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | References                                                                                   |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| <b>Success or failure</b>         | Mixed view on effectiveness and achievement of goals.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                              |
| <b>Independence of evaluation</b> | No consensus in evaluations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                                                                                              |
| <b>Key actors</b>                 | Governments, the ASEAN Secretariat and its agencies, NGOs, foreign governments, industries and international/regional organizations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                                              |
| <b>Baseline</b>                   | The Agreement does not provide a specific baseline.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                                                                              |
| <b>Timeframe</b>                  | The Agreement is expected to remain in force perpetually with the active participation of all ASEAN member states, with the goal of achieving a haze-free ASEAN by 2020.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Haze Action Online 2018                                                                      |
| <b>Constraining factors</b>       | Logging and clearing land by burning creates employment for less fortunate people due to limited employment in other sectors. Oil palm and pulpwood industries have thus largely flourished under weak law enforcement by local authorities. Once cleared to make room for plantations, peat forests tend to smoulder underground for weeks even after surface fires are fully extinguished.                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                              |
| <b>Enabling factors</b>           | Singapore collaborated with Jambi in Indonesia between 2007 and 2011 to implement action programmes to prevent and mitigate land and forest fires. Malaysia cooperated with an NGO, the Global Environmental Centre, to reduce the risks associated with peatland fires. The 2005 cloud-seeding project in Riau and West Kalimantan conducted by Indonesia, Malaysia and Singapore indicated cooperation. An environmental partnership between Singapore and Indonesia from 2009 to 2011 enables fire management and extinction in Riau. The institutional arrangements and collaboration have been key enabling factors, as was the willingness of the Parties to commence action even prior to Indonesia's ratification. Programmes to improve peatland management and control haze pollution have been welcomed by member states. | Haze Action Online 2017                                                                      |
| <b>Cost-effectiveness</b>         | The cost of 2010–2014 ASEAN Peatland Forests Project was US\$5.9million. The project successfully scaled up the management and rehabilitation of critical sites in Philippines and Viet Nam. An estimate of the cost to control Indonesian haze is put at US\$5.7 billion, and another to address forest fires is US\$1.2 billion, but this does not include losses from peatland burning, which the World Bank puts at US\$16 billion for the 2015 fires alone.                                                                                                                                                                                                                                                                                                                                                                     | World Bank 2016; Nazeer and Furuoka 2017; Hans 2018                                          |
| <b>Equity</b>                     | Haze contributes to respiration difficulties and other haze-related illness, particularly in children and in poor people.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Malaysian Nature Society Science and Conservation Unit 1997; Gordon, Mackay and Rehfues 2004 |
| <b>Co-benefits</b>                | Associated impacts from haze include CO <sub>2</sub> emissions, losses of wildlife and potential benefits from nature preservation and biodiversity; impacts are linked to the Sustainable Development Goals such as goals 3, 11 and 12. The ASEAN peatland management strategy and the SEA peat project include contributions to climate change mitigation (2006–2020). The Agreement is relevant to the achievement of national air quality targets. E.g., in Singapore, where targets for 2020 have been adopted, effective management of peatlands and the control of haze pollution in neighbouring countries have a direct impact on the quality of air.                                                                                                                                                                       | Asia Pacific Clean Air Partnership [APCAP] 2015, p. 2; World Wide Fund for Nature [WWF] 2018 |
| <b>Transboundary effects</b>      | Smoke from wildfires and burning agricultural waste travels to and adversely affects other countries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                              |
| <b>Possible improvements</b>      | Development of a zero-burning policy, accomplishment of ASEAN Community Vision 2025, and raising political will for further cooperation; could gain potential benefit through collaboration with other initiatives such as the Acid Deposition Monitoring Network in East Asia, the Climate and Clean Air Coalition and the Asian Co-benefits Partnership.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                              |

Haze is a health issue, worsening existing heart and lung conditions (WHO 2016). It caused acute respiratory infections in over 500,000 people and 19 deaths in 2015. The economic cost was estimated at US\$16 billion, affecting the transportation (US\$372 million), tourism (US\$399 million), trade (US\$1.3 billion), manufacturing and mining, and mass education sectors (World Bank 2016, pp. 1–2, 4–8). Emissions from burning peatlands contained 90 gases with high levels of toxicity from formaldehyde, acrolein, benzene, carbon monoxide and nitrogen dioxide (Stockwell *et al.* 2016).

The first severe haze episode in 1997–1998 called for regional action. Following the Asian Development Bank's major damage assessment (Qadri *ed.* 2001), the ASEAN Agreement on Transboundary Haze Pollution was adopted in 2002 and entered into force in 2003 (Haze Action Online 2018; UNEP 2010).

The Agreement attempts to change the governance arrangements towards an ASEAN haze-free region by preventing and monitoring transboundary haze pollution as a result of land/forest fires mitigated through concerted national efforts and intensified regional and international cooperation. (ASEAN Agreement on Transboundary Haze Pollution). The ASEAN Specialised Meteorological Centre has been mandated as the regional centre to monitor and assess the weather and smoke haze situation and provide early warning on the occurrence of transboundary haze. Malaysian Meteorological Department provides information on fire risk through a Fire Danger Rating System. National Monitoring Centres are designated within each country to monitor the fire and haze situation locally (Velasco and Rastan 2015).

There are mixed views on the effectiveness of the Agreement in achieving its goals. In 2003, it became the first regional environmental agreement under ASEAN to enter into force, but not all ASEAN countries ratified the agreement until 2014. Some international cooperative activities and national policies were initiated following entry into force, but major haze events have continued to occur, with notable episodes in 2013 and 2015. Like many MEAs, the Agreement has no sanctions clause on failure to meet stipulated obligations.

Some progress has been observed since 2015. Brunei has developed its own transboundary haze forecasting system.

Singapore has enacted a law to enhance the country's ability to deal with transboundary haze by holding companies accountable for haze pollution in Singapore due to activity which had occurred within or outside of Singapore. Indonesia implemented regulations to protect primary forests and peatland, building on a moratorium on new concessions started in 2011. This policy is expected to avoid 7.8 Gt of CO<sub>2</sub> emissions by 2030 (Republic of Indonesia 2015, pp. 5–6).

Activities under the Agreement can also support other cooperation in the region, not least the coordination of monitoring networks, such as through the Asia Pacific Clean Air Partnership (APCAP). APCAP brings together the ASEAN Haze Agreement, the Malé Declaration, the East Asia Network for Acid Deposition and the Atmospheric Brown Cloud initiatives.

## 12.3 Indicators

As discussed in Chapter 5, atmospheric change (including air pollution, climate change, stratospheric ozone depletion and PBT pollution) is directly or indirectly related to each of the SDGs (see Figure 5.2). These issues are also addressed by a collection of global and regional MEAs, as well as policies at the national, provincial and municipal level. To evaluate the effectiveness or sufficiency of any given policy or suite of policies, it is useful to have measurable indicators. Ideally, such indicators should be sensitive to the policy changes of interest but not confounded by other influences. However, the indicator should also be relatable to impacts of the policy change that society values. These two objectives point to either end of the DPSIR framework (Figure 1.2) used in the preceding chapters, suggesting that selecting one best indicator is often a compromise. The compromise might be different if the intent is to evaluate the effectiveness of a specific policy (such as in the case studies above) versus the sufficiency of a suite of policies (including policies at different geographical scales).

This section describes three indicators of atmospheric change that are intended to track progress towards the SDGs and compare the sufficiency of existing policies at the national scale. The indicators chosen focus on air pollution, stratospheric ozone depletion and climate change. The data available for emissions and concentrations of PBTs are not sufficient for evaluating the effectiveness of policies globally or at the national level.

### 12.3.1 Indicator 1: Population-weighted annual mean concentration of PM<sub>2.5</sub>

Figure 12.2: Population-weighted annual country-wide mean concentration of PM<sub>2.5</sub> in 2016

This map combines data from satellite observations, surface monitors and an atmospheric chemistry and transport model.

Source: Adapted from Health Effects Institute (2017); Shaddick *et al.* (2018).

#### Policy relevance/causal chain

PM<sub>2.5</sub> concentrations are state variables that are driven by emissions of pollutants, but also by meteorology and climate. PM<sub>2.5</sub> is directly emitted but also formed in the atmosphere from emissions of precursor gases. Policies impact PM<sub>2.5</sub> concentrations by changing emissions and, over the long term, climate. PM<sub>2.5</sub> concentrations are related to exposures and impacts on human health, ecosystems, visibility and short-term climate forcing.

Ambient PM<sub>2.5</sub> concentrations can be monitored at surface locations and also estimated from observations from satellite-based instruments. The best characterization of the distribution of PM<sub>2.5</sub> concentrations is developed by combining information from surface observations, satellite observations and computer models. The resulting concentration field can be combined with the population distribution to estimate the population-weighted annual average.

Exposure to PM<sub>2.5</sub> concentrations leads to a variety of human health impacts, including premature mortality. Weighting the average concentration by population distribution creates an indicator that is focused on the concentrations to which people are exposed.

Emissions of PM<sub>2.5</sub> and its precursors come from a wide variety of anthropogenic sources, including electricity generation, transportation, residential combustion, industrial processes and agricultural burning. These sources can be managed using a wide variety of policy approaches.

#### Other factors

PM<sub>2.5</sub> concentrations are also affected by weather, wildfires, windblown dust and volcanoes. Weather is subject to significant inter-annual variability, decadal cycles and long-term trends. The contributions of wildfires, windblown dust and volcanoes also vary from year to year. These influences must be accounted for when attributing observed trends to the impact of control policies.

Observed trends can be quantitatively apportioned to changes in anthropogenic emissions, natural emissions and weather, using computer models of atmospheric chemistry and dynamics. However, the uncertainty in model estimates can be as large as the impact of a change in policy.

#### Possible alternatives

PM<sub>2.5</sub> concentrations are well-accepted metrics for air pollution. WHO has established a guideline value and interim targets for maximum annual average PM<sub>2.5</sub> concentrations. Under the SDGs, the population-weighted annual mean level of PM<sub>2.5</sub> or PM<sub>10</sub> was selected as an indicator of progress towards sustainable cities. Weighting concentrations by the population exposed focuses the metric on the overall impact on the population. However, a population weighted average may mask the number of people exposed to the most extreme air pollution levels. Thus, absolute concentrations provide another alternative metric.

Direct emissions of PM<sub>2.5</sub> and its gaseous precursors (including SO<sub>2</sub>, NO<sub>x</sub> and NH<sub>3</sub>) are alternative indicators. Emissions are more directly affected by policy changes, but more distantly related to health impacts. For many sources, measurement of emissions is impractical, and estimates are highly uncertain.

Figure 12.3: Ozone-depleting substance consumption in ozone depletion tons in 2016

Source: UNEP (2017)

#### Policy relevance/causal chain

The manufacture and use of ODSs lead to emissions that affect the concentration of ozone in the stratosphere and, as a result, the level of ultraviolet (UV) radiation reaching the Earth's surface. Increases in UV exposure adversely affect human health and ecosystems. ODSs vary in the extent to which they deplete stratospheric ozone. The effectiveness of policies to limit the manufacture and use of ODSs can be measured using ODS emissions estimates weighted by the ozone-depleting potential (ODP) of each compound (2014). ODP-weighted ODS emissions are reported to the Secretariat of the Vienna Convention and Montreal Protocol.

#### Other factors

ODS emissions are directly linked to the effectiveness of policies to eliminate their manufacture, use and improper disposal.

The relationship between ODS emissions, stratospheric ozone concentrations, UV exposures and health effects can

be estimated using models which account for atmospheric chemistry and dynamics, exposure behaviours and population characteristics. These model estimates can be evaluated by comparing them to observed ozone concentrations, UV levels and disease incidence rates.

#### Possible alternatives

Other metrics have been used to gauge the success of efforts to protect stratospheric ozone, including the minimum observed stratospheric ozone concentration, changes in UV radiation levels and the spatial extent of the Antarctic ozone 'hole'. These metrics are influenced by ODS policies over the long term, but also by inter-annual variability, decadal climate cycles and long-term climate change.

ODS emissions could be compared on a per capita or per gross domestic product (GDP) basis, each of which implies a different assumption about what constitutes an equitable distribution of the burden of additional controls.

### 12.3.3 Indicator 3: Anthropogenic emissions of long-lived greenhouse gases (CO<sub>2</sub> equivalents)

Figure 12.4: National total GHG emissions in 2014 in MtCO<sub>2</sub>e, including land-use change and forestry sources and sinks

Source: World Resources Institute (2017). Climate Analysis Indicators Tool: WRI's Climate Data Explorer. Washington, DC: World Resources Institute. Available at <http://cait.wri.org/historical/>. Note these are derived from several sources including Food and Agriculture Organization of the United Nations [FAO] 2016; IEA 2016; UNFCCC 2017b).

#### Policy relevance/causal chain

Long-term climate change is primarily driven by emissions of GHGs, including CO<sub>2</sub>, methane (CH<sub>4</sub>), nitrous oxide (N<sub>2</sub>O) and fluorinated gases. The contribution of each of these pollutants to climate change can be compared in terms of CO<sub>2</sub> equivalents using the Global Warming Potential (GWP) index, which accounts for the pollutants' different atmospheric lifetimes. GWPs are calculated for a specific time-horizon, with 100 years being the most common for comparing the impact of long-lived GHGs.

Anthropogenic emissions of GHGs come from a wide range of sources but are primarily associated with the production and consumption of energy, land-use change and deforestation. Different types of policies can directly or indirectly affect energy production and consumption behaviours and technologies and thus the generation of GHG emissions. Anthropogenic emissions are quantified and reported at the national level to the UNFCCC and provide an aggregate indicator of the effectiveness of policies. Annual emissions data from 1990 to the present are available from the UNFCCC for industrialized countries or economies in transition (called Annex I Parties under the Convention). Under the Paris Agreement, all countries are required to submit emissions inventories every two years.

#### Other factors

In addition to policies, anthropogenic GHG emissions are also affected by economic, social and technological trends. GHG emissions are also generated by natural sources. Both natural and anthropogenic sources are affected by natural meteorological and climate variability.

The relationship between GHG emissions, radiative forcing, changes in climate and climate variability and downstream impacts on human health, ecosystems and infrastructure can be estimated using Earth system models that must account for a significant number of processes and feedbacks.

GHG emission estimates can be compared to observations of GHG concentrations from *in situ* measurements and satellite-borne instruments, although it can be difficult to attribute small changes in specific anthropogenic sources to changes in the observed distribution.

#### Possible alternatives

GWP-weighted long-lived GHG emissions are well-accepted metrics of climate policy effectiveness under the UNFCCC.

There are long lag times between changes in emissions and changes in atmospheric concentrations, radiative forcing or climate state variables (temperatures, precipitation etc.), which make these state variables less useful for assessing policy effectiveness.

Emissions of short-lived climate pollutants (such as black carbon and hydrofluorocarbons) could be included in the aggregation, and other indices (such as a Global Temperature Potential (GTP) or a GWP over a 20-year horizon) could be used to weight the contribution of different pollutants.

GHG emissions could be compared on a per capita or per GDP basis, each of which implies a different assumption about what constitutes an equitable distribution of the burden of additional controls.

## 12.4 Discussion and conclusions

A wide variety of policy approaches, including but not limited to planning regimes, emissions and technology standards, market interventions, public information and international cooperation, have been applied to the problems of air pollution, climate change, ODSs and PBTs. Lessons can be learned about each type of policy approach from applications to the four different problems at different geographical scales.

One lesson is that policy approaches must be adapted to specific contexts. There is no single model policy that is most appropriate for all settings. High-income countries rely on information-rich planning regimes and regulatory approaches backed by government enforcement capacity. These approaches may not be the most appropriate for settings where information is poor and enforcement capacity is lacking. In such settings, voluntary standards, market

interventions and public information may prove more effective in decreasing emissions and hazardous exposures. To improve the effectiveness of such attempts to strengthen climate finance and reduce air pollution, development assistance will play a crucial role in capacity-building and green economy development. Capacity-building should focus on strengthening the technical and planning capabilities at local and national levels that are most relevant for anticipating the potential impacts of climate change and developing appropriate policy responses. Air quality measures need to be combined with climate and energy measures, agricultural policy, transport policy and urban planning, with a focus on improving health and biodiversity. A key message and challenge is how to ensure that climate policies do not increase health risks (e.g. from biomass burning and diesel) and that air quality policy is climate neutral. Also, it is imperative to consolidate a multi-scale governance approach that aligns international, national and local actions (Maas and Grennfelt eds. 2016).

# Chapter 13

## Biodiversity Policy

© Dr Nibedita Mukherjee

**Coordinating Lead Author:** Diana Mangalagiu (University of Oxford and Neoma Business School)

**Lead Authors:** Nibedita Mukherjee (University of Cambridge and University of Exeter), Dolores Armenteras Pascual (Universidad Nacional de Colombia), Jonathan Davies (University of British Columbia), Leandra Regina Gonçalves (University of Campinas), Jeremy Hills (University of the South Pacific), Louise McRae (Zoological Society of London), Peter Stoett (University of Ontario Institute of Technology)

**Contributing Authors:** Irene Dankelman (Radboud University), Souhir Hammami (Freie universität Berlin), Caradee Wright (South African Medical Research Council), Carol Zastavniouk (Golder Associates Ltd)

# Executive summary

**Biodiversity is a key component of a healthy planet with healthy people** (*well established*). Though evidence regarding the importance of biodiversity for economic output, health and security has grown significantly in the last two decades, it is certain that existing measures to conserve and sustainably manage biodiversity are inadequate {Box 13.1, Section 6.1, 13.1}.

**Policy instruments working in silos are insufficient to stem biodiversity loss** (*well established*). Instead, multiple approaches that embrace a diversity of instruments and scales, including platforms for encouraging behaviour change, are vital {13.1, 13.2.3}.

**The cost of inaction (societal and economic) for biodiversity conservation and restoration is extremely high**, as biodiversity loss is largely irreversible (*established but incomplete*) {13.1, 13.2.1, 13.2.4}.

**There is an urgent need to act now and strengthen policy responses for conserving biodiversity** and invest in capacity-building and institutional infrastructure to reach the Aichi targets and Sustainable Development Goals (*well established*) {13.3, 13.4.2}.

**Current valuation methods are not adequate to account for the negative impacts of biodiversity loss** (*well established*). Developing appropriate valuation metrics and methods to make the multiple values of biodiversity understandable to decision makers is urgently needed (e.g. natural capital accounts). Such valuation techniques should consider the full natural capital value at the national level and integrate it into their National Biodiversity Strategic Action Plans {13.2.4}.

**Mainstreaming biodiversity should be promoted by all stakeholders, including governments and the private sector, across themes such as health, agriculture, social security, trade and education** (*well established*) {13.2.2, 13.2.3, 13.2.4}.

**There is a lack of baseline information to measure the success or failure of most biodiversity policy and governance interventions** (*well established*). Investing in long-term research programmes would be useful, particularly in biodiverse developing nations, to develop effective baselines. In addition, a well-defined time frame to turn goals into actions will be very likely to be useful for effective conservation policy implementation {13.2}.

**Investing in independent monitoring and cost-benefit analysis could help in measuring policy effectiveness** (*well established*). Countries could integrate autonomous monitoring and evaluation in the implementation of programmes to improve effectiveness. As a start, building an evidence base of what works in conservation could be prioritized at a national level {13.2}.

**Conservation problems require long-term solutions, while conservation and research funding is usually short term** (*well established*). Addressing this **timescale mismatch** is urgently needed in the design phase of policy interventions {13.2.3}.

**Policies and mechanisms need to be in place to support innovative measures to strengthen biodiversity protection**. For example, while traditional approaches such as protected areas have been the norm to secure tenure, other forms of arrangements such as community-based protected areas (e.g. Locally Managed Marine Areas) are needed to supplement protected areas for conserving biodiversity in the long term {13.1}.

**Economic development is commonly perceived as a threat to biodiversity conservation, but sustainable growth and development of the green economy (low in carbon, resource-efficient and socially inclusive) can also promote and enhance biodiversity** (*well established*) {13.2.3, 13.2.5}.

**In the policy design phase, adequate attention needs to be paid to equity, gender and health aspects** (*well established*). To deliver desired co-benefits between enhanced biodiversity and other environmental and societal goals, there is a need for scale-up, further innovation and transformation in the approach to biodiversity management. It would also help other sectors achieve their goals through biodiversity conservation. This reflects Sustainable Development Goal (SDG) 17, which calls for the building of partnerships to achieve the SDGs. {4.2, 13.1, 13.2.4}

**The astounding wealth of biodiversity that we collectively share is on loan from future generations**. To create the future we want, member states, community-based organizations, non-governmental organizations and corporations are urged to create financial and social incentives that enable individuals and policymakers to make decisions that favour the protection and promotion of biodiversity {13.2.2, 13.2.3, 13.2.4}.

### 13.1 Introduction

Biodiversity is an integral facet for achieving a healthy planet and human well-being (Cardinale *et al.* 2012; World Health Organization [WHO] and Secretariat of the Convention on Biological Diversity [SCBD] 2015). However, the rate of biodiversity loss continues unabated, and it is well known that species extinction risks are increasing over time (see Section 6.1). The estimated annual cost to the global economy from biodiversity loss and loss of ecosystem functions is up to €14 trillion by 2050; this is equivalent to 7 per cent of projected global gross domestic product (GDP) (Braat and ten Brink (eds.) 2008). Another estimate places the global cost from the loss of ecosystem services solely from land-use change at US\$4.3–20.2 trillion (in 2007 valuation) per year between 1997 and 2011 (Costanza *et al.* 2014). Though it is impossible to be precise, quantifying the costs of inaction motivates the need for policy action (Braat and ten Brink (eds.) 2008; Oliver *et al.* 2015). In addition, the importance of biodiversity to health in all its dimensions (WHO and SCBD 2015) has emerged in initiatives such as ecosystem approaches to health, Ecohealth, One Health and Planetary Health (see Section 4.2.1). There is a growing focus on interrelationships between the health of humans, domesticated and wild animals and other species in the context of complex social-ecological systems (Charron 2012; Wilcox, Aguirre and Horwitz 2012; WHO and SCBD 2015) (**Box 13.1**).

Biodiversity loss is a complex issue (see Section 6.1), and biodiversity conservation relies on strategies involving a wide range of policy approaches such as regulatory command and control, economic incentives, supporting investment, the promotion of innovation, enabling actors, capacity-building and goal-setting, among others. The major policy and governance responses include the Convention for Biological Diversity (CBD) (CBD 1992), the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES) and protected areas (see Section 6.7). While there are variations in the effectiveness and perceived legitimacy of international environmental agreements (IEAs) and multilateral environmental agreements (MEAs) (see Annex 6-1 for a list of MEAs relevant

#### Box 13.1: Global recognition of the link between human health and biodiversity.

A joint work programme between CBD and WHO was formally established in 2012 (CBD 2012 (Decision XI/6)). Health was identified as a priority mainstreaming sector at the 13th CBD Conference of the Parties (CoP) in Mexico in December 2016 (CBD 2016a (Decision XIII/3)); a comprehensive decision to integrate biodiversity and health linkages in national policies was also adopted (CBD 2016b (Decision XIII/6)). The United Nations Environment Programme (UNEP) GEO-6, 'Healthy Planet, Healthy People' and the joint WHO-CBD publication 'State of Knowledge Review Connecting Global Priorities' (WHO and SCBD 2015) recognize that human health and biodiversity are inextricably linked. At the 71st World Health Assembly in 2018, biodiversity loss was recognized as a significant human health issue by many Member States. Increasingly, the medical, public health, biodiversity conservation and policy communities are forging new networks and breaking traditional silos, and One Health, Ecohealth and Planetary Health have emerged as animating approaches.

to biodiversity at the end of this document), they form the basis of global environmental governance and continue to shape governmental behaviour and expectations (Stoett 2012). Biodiversity has more MEAs in place than other environmental policy domains (see Annex 13.1).

Over the last 10 years, and particularly since the last GEO, awareness about the loss of biodiversity has risen significantly in international policy, health and economic discourse (WHO and SCBD 2015; Jabbour and Flaschland 2017; World Economic Forum 2018). The most recent developments in the global biodiversity policy and governance landscape are described in Annex 13.2 at the end of this document.

The 196 CBD member states are required to develop National Biodiversity Strategies and Action Plans (NBSAPs) according to Article 6. To date, 190 of the 196 parties (96 per cent) have developed NBSAPs (SCBD 2018a) (**Figure 13.1**).

Figure 13.1: Cumulative number of countries that have adopted the NBSAPs as of 2018

Source: SCBD (2018a)

Moreover, similar to other environmental issues, biodiversity conservation and restoration require the involvement of a range of different stakeholders with often conflicting value positions (Mukherjee *et al.* 2018). Over time, there has been greater recognition of the gender and equity dimensions of conservation policies and their implementation (**Box 13.2**).

This chapter follows the twofold (top down and bottom up) policy effectiveness assessment framework outlined in Chapter 10.<sup>1</sup>

**Key policies and governance approaches (top down):** A set of policy clusters and five specific policy instruments pertaining to these clusters is elaborated. Five case studies are drawn as illustrative examples of these policy instruments (**Table 13.1**). The case studies are not intended to be representative in any form. They were selected to cover the three dimensions of biodiversity (ecosystems, species and genetics), a range of approaches within the typology, geographical spread of

examples and varying degrees of success (see Section 10.6). The case studies are drawn from North America, South Asia, Europe, the Pacific and Africa.

**Indicators (bottom up):** The case studies are followed by a review of three policy-relevant indicators (see Section 10.7), which map the progress towards internationally agreed goals and targets, complementing the policy and governance approaches above.

## 13.2 Key policies and governance approaches

### 13.2.1 Enabling actors: Community-based conservation

Engaging local stakeholders through community-based conservation is a central feature of many biodiversity conservation and natural resource management efforts globally to make conservation more effective. Within the Drivers, Pressures, State, Impact, Response (DPSIR) framework (see Figure 1.2 Chapter 1), community-based conservation as a policy approach addresses the drivers, as it counterbalances external resource users who do not have the same cultural and historical attachment to the area.

Protected areas are a key tool for biodiversity conservation. There has been a shift over the last few decades away from exclusive protected areas, where humans were not welcome, towards more people-centred or community-based conservation (Brown 2003; Oldekop *et al.* 2015) and integrated landscape management (Food and Agriculture Organization [FAO] 2018). A nuanced understanding of governance and sociocultural context plays an important role in all types of stakeholder engagement efforts for biodiversity conservation (Bennett *et al.* 2017; Mukherjee *et al.* 2018) and makes those efforts more legitimate, salient, robust and effective (Sterling *et al.* 2017).

Communities are the major players in decision-making in indigenous peoples' and community-conserved territories and areas (ICCAs). ICCAs play a key role in conserving traditional ecological knowledge, cultures and languages, which are often inextricably linked to conservation of biodiversity (Corrigan and Hay-Edie 2013). This role helps in addressing CBD Aichi Biodiversity Target 18, which is aimed at preserving traditional knowledge, innovations and practices of indigenous peoples and local communities and integrating them into biodiversity conservation interventions (ICCA Registry 2018).

#### Box 13.2: Highlights of the gender and equity dimensions in biodiversity policies

Paragraph 13 of the CBD Preamble recognizes gender issues in conservation, and the Subsidiary Body on Scientific, Technical and Technological Advice (SBSTTA) mentions women's practices, knowledge and gender roles in food production (SCBD 2018b). The need for the full and active involvement of relevant stakeholders, including indigenous and local communities, youth, non-governmental organizations (NGOs), women and the business community, is underlined in the Convention.

- ❖ The Nagoya Protocol on Access to Genetic Resources and the Fair and Equitable Sharing of Benefits Arising from their Utilization created an international framework that provides concrete measures, rules and procedures.
- ❖ Out of the 254 NBSAP reports from 174 countries, 143 reports (56 per cent of all documents) from 107 countries (61 per cent of all countries examined) contain at least one gender keyword; 145 of the 174 countries (83 per cent) identify gender equality as a guiding principle; and 12 per cent have gender equality or women's empowerment as an objective or goal (International Union for Conservation of Nature [IUCN] 2016; SCBD and IUCN 2018).

**Table 13.1: Typology of policy and governance approaches described in this chapter**

| Policy type /governance approach | Policy instrument(s)               | Case study                                            | Spatial scale |
|----------------------------------|------------------------------------|-------------------------------------------------------|---------------|
| Enabling actors                  | Community-based conservation       | Locally managed marine areas, Fiji                    | National      |
| Command and control              | Policing of illegal wildlife trade | Wildlife trafficking and Project Predator, South Asia | Regional      |
| Economic incentive               | Payment for ecosystem services     | Working for Water programme, South Africa             | Subnational   |
| Supporting investment            | Banking of genetic material        | Svalbard global seed vault, Norway                    | Global        |
| Enabling actors <sup>1</sup>     | Strategic environmental planning   | Urban biodiversity in Edmonton, Canada                | City          |

<sup>1</sup> The policy type 'enabling actors' has been showcased through two different examples of associated policy instruments.

The case study below on Locally Managed Marine Areas (LMMAs) elaborates one such type of community-based sustainable management in the marine realm.

#### **Case study: Locally Managed Marine Areas in Fiji**

Fiji LMMAs are defined as “areas of nearshore waters and coastal resources that are primarily managed at a local level by the coastal communities, land-owning groups, partner organizations, and/or collaborative government representatives who reside or are based in the immediate area” (Figure 13.2). They cover 145 traditionally defined fishing areas (79 per cent of Fiji’s inshore fishing areas); the remaining areas permit comparison of the effectiveness of the approach. The LMMA approach is signified by empowered local actors acting at a community scale to sustainably manage inshore resources for mutual community-wide benefit, most commonly through periodically harvested closures (Jupiter *et al.* 2017). After gaining traction in Fiji, the approach was extended further to Melanesia and Polynesia and into Asia through the LMMA network.

Community-based approaches have garnered support because of their adaptability to different contexts and focus on locally identified objectives, negotiated and implemented by stakeholders. Rather than promoting new and alternative visions for serving short-term human needs, community-based approaches such as the LMMA approach are built on refreshing and revitalizing long-standing traditional systems. The non-prescriptive nature of the approach, however, leads to multiple objectives that confound simple measurement of natural resource and biodiversity outcomes (Jupiter *et al.* 2014). Further benefits of the approach could extend to human health through improved food and nutrition security and community integrity, though this has not been documented to date.

The organic expansion of alternative approaches is a positive indication of their effectiveness. Some management tools used with the LMMA approach, such as periodically harvested

closures, are not consistently effective for fish biomass and biodiversity outcomes (Jupiter *et al.* 2017). While the approach has spatially expanded dramatically in the absence of any alternative and is currently heavily relied on to achieve conservation and fisheries management outcomes in Fiji, there is no unequivocal evidence at present that it has been completely effective in terms of site-based biological outcomes. The approach has transformative potential, through promoting benefits based on a long-established community system strengthened by coherent resource management approaches.

As the costs of both inaction and action are predominately borne by the local community, the incentive for progressive transformation is apparent. Attention needs to be paid to the causality between community-based governance arrangements and the effectiveness of conservation efforts (Eklund and Cabeza 2017). Existing analyses of policy effectiveness, such as the ‘Protected Planet’ report (Bertzky *et al.* 2012; Juffe-Bignoli *et al.* 2014; United Nations Environment Programme World Conservation Monitoring Centre [UNEP-WCMC] and IUCN 2016), could be consulted to identify gaps between policy intent and governance effectiveness.

#### **13.2.2 Command and control policies: Policing of the illegal wildlife trade**

Command and control policies (CCPs) are characterized by centralized, often hierarchical and bureaucratic, decision-making structures that have defined jurisdictional authority and less flexibility in implementation compared to economic incentive policies (Cox 2016). CCPs are the most traditional form of regulatory instruments seeking to ‘control’ activities that could negatively affect biodiversity through penalties, prohibitive rules, enforcement and compliance checks. Typically, national or subnational governments are the decision-making authorities which create the rules and decide how, when and by whom the rules will be implemented (Holling and Meffe 1996). Due to their centralized structure and institutional support, it is easier to evaluate the policy effectiveness of CCPs, especially when the policies have clearly stated objectives and time frames (Gunningham and Young 1997). Therefore, they may be well suited to complex, non-linear issues such as biodiversity loss (e.g. due to ecological tipping points). However, top-down approaches can also present issues of legitimacy, equity and sustainability for local communities (Redpath *et al.* 2017).

Integrating the views of local stakeholders in the decision-making and implementation phases is often key to the success of CCPs (Mukherjee *et al.* 2018). For example, though the European Union (EU)-wide Birds Directive 79/409/EEC (European Council 1979) and the Habitats Directive 92/43/EEC (European Council 1992) engaged several actors in the policy design phase, they are often implemented in an inflexible way at the national level in EU member states (Primmer *et al.* 2014). In Greece, local communities were rarely engaged in the effective implementation and enforcement of EU directives; this led to limited representation of species endemic to Greece in Natura 2000 appendices and inadequate responses (Apostolopoulou and Pantis 2009), conflicts and a lack of trust (Primmer *et al.* 2014). Furthermore, the effectiveness of CCPs (e.g. protected areas) is directly proportional to the capacity and resources available to manage them (Geldmann *et al.* 2018).

**Figure 13.2: Inshore fishing is an important source of food in Fiji, and many of these inshore areas are under traditional tenure by local communities**

**Table 13.2: Summary of assessment criteria: Locally Managed Marine Areas in Fiji case study**

| Criterion                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | References                                                          |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------|
| <b>Success or failure</b>         | The Fiji LMMA approach can increase fish and invertebrate size and abundance. Three of the eight LMMAs studied had fish biomass benefits, and one had biodiversity benefits. This improves the potential for the sustainable use of coastal fisheries resources and, therefore, supports national policy agendas (e.g. Roadmap for Democracy and Sustainable Socio-economic Development and Green Growth Framework) as well as international obligations such as UNCLOS and CBD.                                                                                                                                               | Jupiter <i>et al.</i> 2017                                          |
| <b>Independence of evaluation</b> | Expert-based assessments involved several organizations, including: UN Environment World Conservation Monitoring Centre (UNEP-WCMC), the Centre for Sustainable Development and Environment (CENESTA), the International Union for Conservation of Nature (IUCN), the United Nations Development Programme (UNDP), the Secretariat of the Pacific Regional Environment Programme (SPREP), the South Pacific Community (SPC), the World Wide Fund for Nature (WWF), WorldFish and Reefbase.                                                                                                                                     | Govan 2009; Jupiter <i>et al.</i> 2014; Jupiter <i>et al.</i> 2017, |
| <b>Key actors</b>                 | There is external input from the NGO and community-based organization (CBO) sector guided by local norms. The Government plays no direct role in management approaches and has a passive administrative role such as collection of dues for fisheries permits from non-customary (non-community) fisheries, which are then returned to the community.                                                                                                                                                                                                                                                                          |                                                                     |
| <b>Baseline</b>                   | No baseline data were collected at the start of initiatives. The selection of target areas was based on interest from the community, rather than any particular biological or societal status.                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                     |
| <b>Time frame</b>                 | No time frame was established for the initiative. LMMAs emerged in the 1980s, coupled with a realization of the ineffectiveness of Western approaches to conservation in countries with local tenure and with little ability to enforce conservation measures. Fiji's LMMAs expanded through the 1990s and 2000s to their present coverage of 145 traditional fishing areas covering 79 per cent of Fiji's inshore fishing area.                                                                                                                                                                                               |                                                                     |
| <b>Constraining factors</b>       | While the community may be able to manage local resources, strategies must be implemented that improve management of threats operating at larger scales and across boundaries (e.g. provincial scale, land-sea interactions, climate change).                                                                                                                                                                                                                                                                                                                                                                                  |                                                                     |
| <b>Enabling factors</b>           | The openness of the Fiji LMMA network allowed a wide range of entities to participate in the expansion, including NGOs, universities and CBOs, and facilitated the associated financial support. Working within existing sociocultural norms allowed this inclusive and integrated approach linking communities to natural resources to flourish.                                                                                                                                                                                                                                                                              |                                                                     |
| <b>Cost-effectiveness</b>         | No cost-effectiveness assessment has been conducted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                     |
| <b>Equity</b>                     | Equity gains from the approach include: increased fish and invertebrate size and abundance, which improve diet and also improvement of the potential for the sustainable use of coastal fisheries resources when under LMMA management. However, these biological gains are not guaranteed, and other co-benefits may be more important, such as reinforcing customs and asserting access and tenure rights. This is assumed to be relatively equitable in the way the gains are spread across the communities involved; however, there are sections of the population who are not bestowed with traditional customary rights. | Jupiter <i>et al.</i> 2014; Jupiter <i>et al.</i> 2017              |
| <b>Co-benefits</b>                | The extension to other Pacific countries and Asian countries was not an intended consequence at the start but can be perceived as a co-benefit, additional to those identified at the community level.                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                     |
| <b>Transboundary issues</b>       | There are no intra- or international transboundary issues.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                                     |
| <b>Possible improvements</b>      | There is a need for increased engagement and alignment with government. Government 'ratification' and sustainable financing of support for customary systems delivering natural resource management would help stabilize the approach. Increased clarity in the costs of such approaches and improved monitoring to assess resource management and biodiversity outcomes would be useful.                                                                                                                                                                                                                                      |                                                                     |

The case study below examines the effectiveness of CCPs in the context of addressing the global illegal wildlife trade. The estimated value of illegal wildlife trade ranges between US\$50 billion and US\$150 billion per year (illegal fisheries are estimated at between US\$10 billion and US\$23.5 billion, and illegal logging at between US\$30 billion and US\$100 billion (Nellemann and International Criminal Police Organization [INTERPOL] Environmental Crime eds. 2012; Higgins and White 2016). The corrupt engagement of some government officials, including customs officials and local police, in addition to a chronic lack of resources, make effective monitoring and enforcement difficult. Even in countries with relatively advanced technological and criminological infrastructures, wildlife crime lags behind other aspects of law enforcement (Wellsmith 2011). Violence is not uncommon either, as poaching involves weapons, and anti-poaching efforts can be lethal; armed rebel groups also use the trade to finance their military campaigns.

Within the DPSIR framework (see Section 1.6), this policy approach is mostly aimed at the pressure of overexploitation, by tackling related biodiversity loss or by protecting endemic species and traditional human practices (see Section 6.4.4). However, the development of effective CCPs to constrain undesirable human activities demands significant capacity-building efforts.

#### **Case study: Project Predator and policing the global illegal wildlife trade**

Project Predator was launched in 2011, at the 80th INTERPOL General Assembly in Hanoi, Viet Nam, and is focused on building law enforcement capacity for the conservation of Asian big cats, most notably the tiger. Wild tiger populations

are falling at a precipitous rate, down from over 100,000 at the start of the 20th century to less than 4,000 today (Goodrich *et al.* 2015). The main threat to big cats is habitat destruction, but poaching remains a major problem throughout their range. As reported by the IUCN Red List, the largest market is for tiger bone used in Asian traditional medicines, but other illegal markets for tiger products, especially skins, teeth and claws (particularly in Sumatra), contribute to poaching pressure. Tigers killed by farmers or villagers who believe their livestock or human inhabitants are at risk of tiger attacks can also feed into the illegal trade.

The specific objectives of Project Predator include:

- i. encouragement of the creation of National Environmental Security Taskforces (**Figure 13.3**) and strengthening the South Asia Wildlife Enforcement Network;
- ii. information and intelligence management, and enhancement of investigative skills;
- iii. capacity-building and international integration; and
- iv. intelligence-led anti-poaching activity.

Tiger range States include Bangladesh, Bhutan, Cambodia, China, India, Indonesia, Lao PDR, Malaysia, Myanmar, Nepal, Russian Federation, Thailand and Viet Nam. The collaboration between INTERPOL, national governments and legal systems is a relatively new development in global environmental governance and supports the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) and other international conventions. Similar programmes have been implemented for the ivory trade, hazardous waste, illegal logging, and illegal fishing.

**Table 13.3: Summary of assessment criteria: Project Predator case study**

| Criterion                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | References                                                      |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------|
| <b>Success or failure</b>         | Success refers to empirical evidence of animal parts seized. In 2015, officials organized Operation PAWS (Protection of Asian Wildlife Species) across 17 countries. This led to the arrest of more than 300 wildlife criminals and revealed the location of four wildlife crime fugitives. Officers seized 6 tiger skins and parts, more than 150 common and clouded leopard skins and parts, including 12 big-cat skins, more than 9 tonnes of ivory, 37 rhino horns, more than 2,000 turtles and reptiles, 282 pangolins, 5 tonnes of pangolin meat, and 275 kg of pangolin scales. | INTERPOL 2015                                                   |
| <b>Independence of evaluation</b> | To our knowledge, no formal evaluation of Project Predator has taken place. However, a recent study by the independent wildlife trade monitoring network TRAFFIC emphasizes the need to share intelligence among range States and the potentially helpful role of INTERPOL.                                                                                                                                                                                                                                                                                                            | Stoner <i>et al.</i> 2016                                       |
| <b>Key actors</b>                 | Project Predator's main funders include the United Kingdom of Great Britain and Northern Ireland Government, Environment Canada, the International Fund for Animal Welfare (IFAW), the Smithsonian, USAID and the Global Tiger Initiative. The latter is an umbrella organization formed in 2008 by the World Bank, the Global Environment Facility, the Smithsonian and the Save the Tiger Fund. It is related in turn to the International Tiger Coalition, which comprises some 40 NGOs in 13 tiger range countries. The CITES Secretariat is a formal partner.                     | United States Agency for International Development [USAID] 2016 |
| <b>Baseline</b>                   | Wild tiger populations have fallen from over 100,000 at the start of the 20th century to less than 4,000 today.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Goodrich <i>et al.</i> 2015                                     |
| <b>Time frame</b>                 | Operation Predator was established in 2011. Funding is expected to continue into the 2020s.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                                                 |
| <b>Constraining factors</b>       | Corruption at all levels continues to be a problem, as does the inability to establish environmental crime as a punishable offence in many countries. The transnational environmental crime networks involved in wildlife trafficking are powerful, and their crossover illicit activities are believed to include human trafficking, drug and arms smuggling, money-laundering and extortion.                                                                                                                                                                                         |                                                                 |
| <b>Enabling factors</b>           | International outrage over the fate of wild tiger and snow leopard populations related to the charismatic nature of these iconic species was a motivating factor. Intelligent policing and the introduction of new tracking technology was essential. Since establishing an Environmental Crime Committee in 1992, INTERPOL has become an active agent in efforts to curb and punish transnational environmental crime.                                                                                                                                                                |                                                                 |
| <b>Cost-effectiveness</b>         | Not conducted yet                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                 |
| <b>Equity</b>                     | Problematically, the low-income poacher often assumes the brunt of legal prosecution, while the enriched 'middle man' or purchaser of illicit wildlife trade escapes (including developed nations (United Kingdom of Great Britain and Northern Ireland, United States of America) which continue to trade in 'legal' wildlife when sources are often hard to identify) (Nelson 2017).                                                                                                                                                                                                 |                                                                 |
| <b>Co-benefits</b>                | Big cats are central to ecosystem resilience and biodiversity, so their protection is beneficial to everyone who relies on related ecosystem services. The enhancement of judicial systems through National Environmental Security Taskforces is another main co-benefit.                                                                                                                                                                                                                                                                                                              | Thinley <i>et al.</i> 2018                                      |
| <b>Transboundary issues</b>       | Wildlife trafficking involves a wide variety of international actors, and INTERPOL is unable to monitor them all. Ultimately, the success of anti-poaching efforts will depend on the capacity of national governments to monitor their own borders in a corruption-free context, and to impose serious punishment on offenders.                                                                                                                                                                                                                                                       |                                                                 |
| <b>Possible improvements</b>      | More information is needed on the impact of INTERPOL's interventions and National Environmental Security Taskforces. More accurate tracking of big cat populations would be helpful across the range States. More local community involvement is needed.                                                                                                                                                                                                                                                                                                                               |                                                                 |

Command and control strategies have historically dominated efforts to promote environmental protection. However, they face difficulties in terms of a lack of human resources and local participation (Harrington, Morgenstern and Sterner 2004; Laitos and Wolongevicz 2014). Though CCPs have their fair share of demerits, they may be highly pertinent in situations where critically endangered species and habitats are at stake and their loss is imminent (see Section 6.4.4). For instance, the relaxation of land clearing regulations and

enforcement has led to increased forest loss, particularly in remnant forests (Marcos-Martinez *et al.* 2018). The challenge lies in greater integration of local communities in both the design and implementation phases (Paavola, Gouldson and Kluvánková-Oravská 2009). Adequate, power-neutral consultation of different stakeholders during policy design, and regular monitoring and adaptation could help improve the effectiveness of CCPs for biodiversity conservation. In the United Kingdom of Great Britain and Northern Ireland,

### Box 13.3: The centrality of indigenous peoples and local communities

UN Environment Assembly Resolution 2/14 asked for a review of “best practices in engaging rural communities in wildlife management” (Cooney *et al.* 2018), focused specifically on engaging indigenous peoples and local communities (IPLCs) in combating the illegal trade in wildlife. The report prepared by IUCN and the International Institute for Environment and Development (IIED) concludes that local communities must be central actors in stemming illegal trade and be viewed as stakeholders and not just passive victims or witnesses. Though policing activities are important, they can also be seen as militarized responses that alienate the local communities that have the most to gain from enhanced biodiversity conservation. As the report states, partly as a “result of an increased militarization of poaching, the response [has included] the resurgence of a top-down protectionist approach emphasizing fences and fines, guns and boots. However, unless accompanied by strengthened accountability measures, this can lead to—and has led to—human rights abuses, restricted livelihood options, and hardship for IPLCs [and can drive] disenfranchisement, resentment and anger” (Cooney *et al.* 2018, p. 5).

Community-based approaches demand patience, as local stakeholders need to organize and build their own capacity. Building robust opportunities for IPLCs to be heard and to exercise their rights at all levels is critical in promoting more effective and equitable wildlife conservation strategies.

implementation of the Natura 2000 sites was carried out in an integrated manner, leading to wider acceptance (Primmer *et al.* 2014). If the INTERPOL approaches described above prove successful, they could serve as models for further initiatives aimed at stemming international crime and environmental destruction. In addition, setting up randomized control trials and regularly measuring and reporting on the success or failure of conservation interventions can help monitor effectiveness (Schwartz *et al.* 2017).

#### 13.2.3 Economic incentive policies: Payment for ecosystem services

Economic incentive policies (EIPs) and market-based instruments are arguably more flexible than CCPs and regulatory policies, allowing the development of innovative approaches that reframe the relationship between people and the environment. EIPs are generally a response measure in the DPSIR framework (see Section 1.6) and are based on the assumption that economic incentives can account for market externalities by facilitating pro-conservation behaviour and disincentivizing negative behaviour. Such economic tools can also be used to compensate stakeholders who are negatively affected by biodiversity conservation.

EIPs are, therefore, able to address scale mismatches in biodiversity conservation—for example, where the benefits of conservation are felt at a regional or national scale, while the cost is borne by local communities at a smaller scale. Examples of EIPs include schemes related to REDD+; species enhancement; eco-certification; setting aside agricultural

land; or purchasing public or grant-aided land. Others include conservation easements, incentive payments for organic farming, fiscal/taxation measures and payment for ecosystem services (PES) (UNDP 2017). For instance, municipalities located in the core area of a national park in France now receive an ‘ecological allocation’ for the protection of these areas (General Code for Local Authorities, article L2,334-7). There is also a 20 per cent reduction in the property tax rate for all wetlands in the country (Primmer *et al.* 2014).

PES captures many of the important elements of EIPs. As a policy instrument, PES was first widely implemented on a national scale in Costa Rica (Porrás *et al.* 2013), where it has been operative since 1996, but has since spread to many countries in different forms. Typically, PES rewards local stewards of an ecosystem so that they maintain the natural resources on which they (and often downstream users) depend. Farmers on steep slopes, for example, can be incentivized to return their land to forest cover, so that an important water supply can be protected. In one well-documented example, the city of New York paid landholders in the Catskill Mountains to protect the landscape and thus avoid the greater cost of a new water treatment plant (Appleton 2013). By providing economic incentives to encourage better stewardship of the land, PES enables new actors in biodiversity conservation and simultaneously promotes a more sustainable relationship between people and nature by emphasizing the value of the ecosystem services that biodiversity supports.

However, the effectiveness of PES schemes is an area of current debate, as there are few randomized control studies to evaluate its success (Börner *et al.* 2017). A recent analysis of 38 peer-reviewed articles found that evidence of effectiveness was weak (Gaworecki 2017). Most studies had not compared areas where PES had been implemented with a relevant non-PES control area (Gaworecki 2017), and the more rigorously designed studies showed reductions in deforestation of just a few percentage points. Payments were often too low compared to the opportunity costs of other land uses – for instance, agricultural development – although this does not take into account potential co-benefits. The following case study explores an example of a PES scheme that had dual goals of reducing invasive species (one of the major pressures on biodiversity) and generating employment.

#### Case study: Working for Water programme, South Africa

In South Africa, a major pressure on water resources is imposed by non-native plants, both terrestrial (e.g. *Pinus*, *Acacia* and *Eucalyptus* species that have escaped from commercial cultivation) and aquatic (e.g. water hyacinth [*Eichhornia crassipes*], also a threat to the African Great Lakes) biomes (Chamier *et al.* 2012). In 1995, the South African Government established the Working for Water (WfW) programme to clear invasive species from environmentally degraded water catchments and address social equity issues and unemployment among low-skilled people. WfW focussed mainly on rural women, youth and people with disabilities, by providing them with employment opportunities associated with the removal and control of invasive plants (McQueen, Noemdoe and Jezile 2001). WfW provides one of the longest-running examples of the PES approach linked to employment generation.

**Table 13.4: Summary of assessment criteria: Working for Water case study**

| Criterion                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | References                                                                                                                                                                                                                                                                      |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Success or failure</b>         | The aims of the WfW programme were to enhance water security, improve ecological integrity and restore the productive potential of land, promote sustainable use of natural resources and invest in the most marginalized sectors of South African society. Today, over 3 million hectares have been cleared of alien species (30 per cent of the total affected area in South Africa), showing some success and promise for the future of the policy. Stream flows were increased, although benefits decline over time as vegetation regrows. | Barnes <i>et al.</i> 2007; Bonnardeaux 2012; Jarman and Meijninger 2012; Le Maitre, Gush and Dziki 2015; Scott-Shaw, Everson and Clulow 2017                                                                                                                                    |
| <b>Independence of evaluation</b> | Extensively evaluated in the peer-reviewed scientific literature                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Hobbs 2004; Turpie, Marais and Blignaut 2008; Buch and Dixon 2009; Meijninger and Jarman 2014                                                                                                                                                                                   |
| <b>Key actors</b>                 | WfW's framework comprises the following: <ul style="list-style-type: none"> <li>❖ Inter-ministerial Board (Cabinet ministers chaired by the Minister of Water Affairs and Forestry)</li> <li>❖ Inter-departmental Steering Committee</li> <li>❖ Provincial Steering Committees and Project Steering Committees of relevant stakeholders at local level</li> </ul>                                                                                                                                                                              | McQueen, Noemdoe and Jezile 2001                                                                                                                                                                                                                                                |
| <b>Baseline</b>                   | The report 'Water for Growth and Development in South Africa, Version 6' was the baseline. It reported that 10.1 million hectares (6.8 per cent) of South Africa and Lesotho were invaded by alien plants in 1997, reducing mean annual water flow by 3.3 billion m <sup>3</sup> and resulting in wastage of about 7 per cent of South Africa's water annually.                                                                                                                                                                                | Barnes <i>et al.</i> 2007                                                                                                                                                                                                                                                       |
| <b>Time frame</b>                 | WfW has been operational for over two decades. Measurable ecosystem gains were reported in the few years immediately following implementation.                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                                                 |
| <b>Constraining factors</b>       | The short-term employment and low wage provided by WfW has been suggested as providing only a temporary solution to the chronic problems of unemployment and the skills gap in South Africa.                                                                                                                                                                                                                                                                                                                                                   | Buch and Dixon 2009                                                                                                                                                                                                                                                             |
| <b>Enabling factors</b>           | Effective legislation used in the programme includes the Agricultural Pests Act, Conservation of Agricultural Resources Act, National Environmental Management Act, Environment Conservation Act, National Water Act, and National Veld and Forest Fire Act. WfW maintains a research unit as part of its commitment to the management of invasive alien plants.                                                                                                                                                                               | Venter 2005                                                                                                                                                                                                                                                                     |
| <b>Cost-effectiveness</b>         | There have been several cost-benefit analyses, with differing results, but overall leaning towards this being a cost-effective policy. An important aspect is the high cost of doing nothing. In 1998, the South African Department of Environmental Affairs estimated the cost of controlling invasive plants at R600 million (US\$100 million) a year over 20 years but indicated that this could double within 15 years if appropriate action is not taken.                                                                                 | South African National Biodiversity Institute 2008; Turpie, Marais and Blignaut 2008; South Africa, Department of Environmental Affairs 2010; South Africa, Department of Water Affairs [DWAF] 2010a; DWAF 2010b; McConnachie <i>et al.</i> 2012; van Wilgen <i>et al.</i> 2012 |
| <b>Equity</b>                     | Landowners clearing invasive species through the WfW programme were eligible for tax breaks. The employees clearing invasive species from the landscape (mostly women and disadvantaged people) benefit the most.                                                                                                                                                                                                                                                                                                                              | Turpie, Marais and Blignaut 2008; Buch and Dixon 2009                                                                                                                                                                                                                           |
| <b>Co-benefits</b>                | WfW provides more than 20,000 temporary jobs each year for the most marginalized people who might not have access to any other employment (52 per cent of beneficiaries are women), educates and trains unskilled labourers and assists in community development programmes ( <a href="http://www.dwaf.gov.za/wfw/">http://www.dwaf.gov.za/wfw/</a> ). With a particular emphasis on HIV/AIDS, WfW aimed to provide support for those with a positive diagnosis, and education and training to reduce the risk of transmission.                | Magadlala and Mdzeke 2004                                                                                                                                                                                                                                                       |
| <b>Transboundary issues</b>       | Not applicable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                                                 |
| <b>Possible improvements</b>      | Recommendations include: a) robust ecological indicators to evaluate: (i) the extent of the area treated; (ii) the reduction in the degree of invasion; (iii) the impact on water resources; and (iv) the rate of ecosystem recovery (Levendal <i>et al.</i> 2008); and b) further integration of social development more fully with the programme's environmental goals.                                                                                                                                                                      | Levendal <i>et al.</i> 2008                                                                                                                                                                                                                                                     |

When implemented well, EIPs allow cross-sector integration (e.g. facilitating women's empowerment by controlling invasive species, as shown in the WfW case study), greater stakeholder engagement and multi-level governance. However, a drawback of EIPs stems from the assumption that financial incentives alone will influence the actors to change their behaviour towards a pro-conservation stance. This assumption may lead to further questions on the sustainability of such policies when funding is exhausted. Finding the correct financial tipping point to prevent biodiversity loss and improve human well-being (e.g. correct level of compensation) by matching projected opportunity costs may be challenging. Cost-effectiveness analysis can help find the optimal solution when multiple conservation interventions are possible (Bryan 2010). A further gap in the implementation of EIPs lies in the treatment of landowners as independent and individual decision makers (e.g. in the Finnish 'Nature Values Trading' PES experiment) (Paloniemi and Vilja 2009). However, landowners may be influenced by professional advisers and a range of group-based factors in their decision-making (Mukherjee *et al.* 2016). In addition, the focus should remain on biodiversity conservation rather than simply the benefits derived from it.

Considerable progress has been made in the last couple of years towards mainstreaming the value of nature (e.g. IPBES 2016). A cautionary note though would be to retain the focus on biodiversity. The essence of biodiversity conservation should not be lost in the enthusiasm to value its benefits and services since biodiversity underpins all the services (see **Figure 13.4** below from Kusmanoff 2017, which shows that while the use of economic language has risen, the use of the term 'biodiversity' has declined in Australia).

**Figure 13.4: Usage of the terms containing 'biodiversity', 'econo' and 'ecosystem services' over time in Australian Government environment portfolio media releases (n = 3,553). Error bars indicate 95 per cent confidence intervals based on the ecosystem services framing subsample (n = 516)**

#### 13.2.4 Supporting investment: Banking of genetic material

Currently only a tiny fraction (~0.002 per cent) of global GDP is invested in the conservation of biodiversity (Sumaila *et al.* 2017). Yet sustaining natural capital by meeting the 2020 Aichi Biodiversity Targets would provide monetary and non-monetary gains that far outweigh the costs of achieving these goals (Sumaila *et al.* 2017).

Though progress is slow, some governments are warming to the cause. For example, the New South Wales Government in Australia has set up a Biodiversity Conservation Trust to deliver a comprehensive conservation programme on private land in its 2017-2037 strategy (New South Wales, Office for Environment and Heritage 2017). Government investment of A\$240 million over five years, with A\$70 million in ongoing annual funding, has been earmarked for this project targeting private landholders.

The EU has estimated that the cost of managing the Natura 2000 sites, its protected area network, would amount to €5.8 billion annually, while the benefits range from €200 billion to €300 billion annually and could create 180,000 jobs (Bourguignon 2015). EU LIFE funding (the Financial Instrument for the Environment), launched in 1992, and its successor LIFE+ have co-financed site management, capacity-building, and species action plans. Between 2014 and 2020, €2.6 billion has been earmarked under LIFE for environmental protection, half of which is for nature and biodiversity conservation (Bourguignon 2015). The United Kingdom of Great Britain and Northern Ireland Government recently announced that it would set up a Green Business Council to support environmental entrepreneurialism in its 25-year Environment Plan (United Kingdom [UK], Department for Environment, Food and Rural Affairs 2018, p. 150). The United Kingdom of Great Britain and Northern Ireland also plans to create a Natural Environment Impact Fund to issue a variety of loans and grants at submarket rates that could be repaid on a long-term basis. This is aimed at addressing potential market failures that might have limited the uptake of return-generating natural environment projects in the past (UK Department for Environment, Food and Rural Affairs 2018, p. 149).

Sources of financing for investment in biodiversity can come from multiple sources (SCBD 2012), including core national biodiversity funding sources, national government financing, international flows of Official Development Assistance and multilateral funding. In addition, tax breaks for green infrastructure, conservation agreements, carbon offsets, green fiscal policies and green bonds, as well as private- and third-sector investment are also in the toolkit available to policymakers to support investment in biodiversity conservation.

The Green Bond principles of 2016 explicitly recognize biodiversity conservation as one of the categories eligible for funding (GreenInvest 2017). Green Bonds are one of the fastest growing fixed-income market segments, with US\$81 billion in 2016. These Green Bonds could be used strategically by governments and corporations to tap international capital to support investment in biodiversity conservation (GreenInvest 2017). Green Bonds could also provide a platform for interactions between financial and investment policymaking,

which are often institutionally separate in some countries (GreenInvest 2017, p. 40).

An innovative example of supporting investment is the Svalbard Global Seed Vault (SGSV), which is a gene bank representing the largest collection of crop diversity in the world. Within the DPSIR framework (see Section 1.6), this serves as a policy response focused on *ex situ* conservation of seeds to improve the status of plant species important for food and agriculture.

#### Case study: Svalbard Global Seed Vault

FAO estimates that 75 per cent of plant genetic diversity was lost in the last century (FAO 2010). A primary form of conservation for plant genetic material is *ex situ* in the form of gene banks (currently over 1,750 worldwide, collectively maintaining an estimated 7.4 million accessions) (FAO 2010).

The SGSV (Figure 13.5) was established in 2008 with the primary goal of providing a backup for plant genetic resources for food and agriculture. The priority is on preserving intraspecific diversity of crop species and crop wild relatives. The risks from natural disaster, war and the mismanagement of some national gene banks demand backup storage for globally important crops (Fowler 2008).

The construction was funded by the Norwegian Government at a cost of US\$8.8 million (Hopkin 2008), and the operating costs for the SGSV are around US\$300,000 annually, shared by the Norwegian Government and Global Crop Diversity Trust. The latter provides long-term grants from an endowment fund built by public and private donations.

**Figure 13.5: The SGSV is located 100m inside a mountain on a remote island in the Svalbard archipelago, midway between mainland Norway and the North Pole, and the samples are stored at -18°C**

Supporting investment policies are urgently needed to complement CCPs, EIPs and enabling actors in stemming rates of biodiversity loss (see Section 6.5). Similar to EIPs, the supporting investment policies are also more flexible and adaptable in their approach. They also allow for unique and innovative solutions as shown in the SGSV case study. Foreign direct investment to developing tropical countries could be directed for biodiversity conservation through supporting investment policies, such as Green Bonds (GreenInvest 2017). Initiatives such as the SGSV are in line with Sustainable Development Goal (SDG) 16, as the outputs of such investments are accountable, transparent and inclusive. One concern, however, is the power structure inherent in the decision-making and implementation of supporting investment policies. Who invests and who benefits in the long term are key questions to be asked in *ex ante* analysis of such policies.

In terms of wider biodiversity conservation, the SGSV is a backup, and it does not seek to maintain the traditional knowledge for harvesting crops that could be lost as agriculture evolves, whereas *in situ* conservation could sustain these skills and also allow species to adapt to changes in their environment. *Ex situ* conservation also faces the issue of genetic erosion (van de Wouw *et al.* 2010), whereby the seeds being conserved may not be viable in perpetuity. Protection of genetic resources requires a range of actors to be involved, as there are political, ethical and technical challenges to be overcome in the conservation of crop genetic resources (Esquinas-Alcázar 2005).

In addition, the contribution of biodiversity to food security needs to be mainstreamed. The Ecosystem Based Adaptation for Food Security (EBAFOSA) initiative was launched in 2015. It aims to reconcile the sustainable management of ecosystems (including the conservation of biodiversity) with adaptations to climate change to ensure food security in Africa.<sup>2</sup>

#### 13.2.5 Enabling actors: Strategic environmental planning

The enhancement of the quality of urban environments for ecological and social benefits is becoming widely accepted as a critical component of urban planning. The United Nations General Assembly (A/71/266 of 1 August 2016) has discussed the 'Mother Earth' concept under 'harmony with Nature', seeking to inspire citizens and societies and change the way they interact with the natural world. This links closely to the concept of green infrastructure, green spaces and the recognition of the vital connections between the ecosystem services and biodiversity. These include benefits linked to water quality, flood attenuation, improved air quality, physical and mental health and noise reduction, all of which are important in reducing problems posed by urban living (Carrus *et al.* 2015; Ürges-Vorsatz *et al.* 2018) and in contributing to climate change mitigation and adaptation (Rosenzweig *et al.* 2018). Biodiversity's role in cities has also been recognized by other international forums, such as the Intergovernmental Panel on Climate Change (IPCC) cities conference in March 2018; experiencing biodiversity has been proven to improve life quality, human health and environmental consciousness in urban areas (WHO and SCBD 2015; Ürges-Vorsatz *et al.* 2018).

**Table 13.5: Summary of assessment criteria: Svalbard Global Seed Vault case study**

| Criterion                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                        | References                                               |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| <b>Success or failure</b>         | The target is to hold 4.5 million varieties of crops, with each variety having 500 seeds on average (a total of 2.5 billion seeds). In the first five years of operation, 53 of the world's gene banks had deposited a substantial part of their collections, and the vault currently contains over 960,000 samples.                                                                                                               | Westengen, Jeppson and Guarino 2013; Asdal 2018          |
| <b>Independence of evaluation</b> | The formal assessment was published in a peer-reviewed journal.                                                                                                                                                                                                                                                                                                                                                                    | Westengen, Jeppson and Guarino 2013; Asdal 2018          |
| <b>Key actors</b>                 | Actors include the FAO Commission on Plant Genetic Resources, the Norwegian Government, the Nordic Genetic Resource Centre, the Global Crop Diversity Trust and the International Advisory Council (technical and policy experts representing FAO, national gene banks, the Consultative Group on International Agricultural Research and the International Treaty on Plant Genetic Resources for Food and Agriculture).           | Westengen, Jeppson and Guarino 2013; Asdal 2018          |
| <b>Baseline</b>                   | Five benchmarks assessed the duplication covered by the collection in the SGSV. This assessment aimed to quantify how far the SGSV is away from its target of duplicating all the distinct accessions (unique sample of seeds) of plant genetic resources for food and agriculture conserved as orthodox seeds (those that can survive drying or freezing) globally.                                                               | Westengen, Jeppson and Guarino 2013; Asdal 2018          |
| <b>Time frame</b>                 | The vault theoretically has a permanent lifetime. Currently, there are a third of globally distinct accessions of 156 crop genera.                                                                                                                                                                                                                                                                                                 | Westengen, Jeppson and Guarino 2013; Asdal 2018          |
| <b>Constraining factors</b>       | The willingness of countries to sign up (e.g. China and Japan) was identified as a constraint, although new seed samples were deposited from countries including India, Peru and Kenya in 2018. Changes in climate could be seen as a future constraint to the facility.                                                                                                                                                           |                                                          |
| <b>Enabling factors</b>           | Signing of the International Treaty on Plant Genetic Resources for Food and Agriculture; permafrost offers natural freezing in case the cooling equipment breaks down; geopolitical stability and a supportive local government (military activity is prohibited under the International Treaty of Svalbard)                                                                                                                       |                                                          |
| <b>Cost-effectiveness</b>         | None conducted so far                                                                                                                                                                                                                                                                                                                                                                                                              |                                                          |
| <b>Equity</b>                     | Currently, plants for traditional use and their cultivation practices are not prioritized, and they might also be vulnerable to loss. The Global Crop Diversity Trust provides funding for developing countries to assist in the logistics of transporting accessions to the SGSV.                                                                                                                                                 | Eastwood <i>et al.</i> 2015                              |
| <b>Co-benefits</b>                | The SGSV has helped raise public awareness (particularly promoted by the media) of the importance of conserving genetic diversity—especially plants—for future food security.                                                                                                                                                                                                                                                      | Friel and Ford 2015; Westengen, Jeppson and Guarino 2013 |
| <b>Transboundary issues</b>       | The SGSV's Standard Deposit Agreement ensures that the legal ownership of accessions cannot be transferred and that accessions can only be returned to the gene banks that originally supplied them.                                                                                                                                                                                                                               | Westengen, Jeppson and Guarino 2013                      |
| <b>Possible improvements</b>      | 1) Gaps in accessions from other gene banks which have no backup collection. 2) The importance of <i>in situ</i> conservation to complement <i>ex situ</i> approaches has also been highlighted, as stored genetic material is evolutionarily static and cannot adapt to changes in climate and habitat. 3) Another form of <i>ex situ</i> conservation—DNA banks—could be a complementary approach to plant genetic conservation. | Dulloo 2015; Hopkin 2008; Hodkinson <i>et al.</i> 2007   |

Engaging communities in effective land use and management of natural ecosystems in urban areas can be beneficial to both residents and biodiversity and promote inclusive city governance. The involvement of different stakeholders at different scales and partnerships between experts from various disciplines (e.g. ecologists, urban designers, landscape architects) is also considered important for biodiversity conservation (Felson and Pickett 2005; Colding 2007). Progress is measurable: for example, the City Biodiversity Index, which “provides a monitoring tool to assist local authorities to evaluate their progress in urban biodiversity conservation, which can be further included in national reports” (CBD 2014).

Various institutional arrangements and approaches take into account the importance of biodiversity in green areas. For example, in Italy health and well-being aspects (Carrus *et al.* 2015), in Brazil restoring Atlantic Forest in urban areas through municipal plans (Sansevero *et al.* 2017), and in Finland preservation of ecosystem services (Niemelä *et al.* 2010) are considered. Mainstreaming biodiversity requires the integration of biodiversity and environmental components and norms into sectoral policies, enabling stakeholders’ involvement. Within the DPSIR framework (Section 1.6), mainstreaming is a response made by a group of actors to address pressures and drivers such as habitat loss and fragmentation and human population pressure (Section 2.2). The Edmonton Natural Area System Policy shows how to engage local actors to mainstream biodiversity into the urban environment.

#### **Case study: Edmonton Natural Area Systems Policy**

The City of Edmonton has made biodiversity protection a priority by integrating biodiversity considerations into urban planning. In 2006 it approved its Environmental Policy to promote the development of environmentally sustainable communities. In 2007, the city approved its Natural Area

**Figure 13.6: The City of Edmonton: the River Valley park system along the North Saskatchewan River as seen from downtown Edmonton**

Systems Policy with a clear goal to “conserve, protect, and restore Edmonton’s biodiversity, and to balance ecological and environmental considerations with economic and social considerations in its decision-making”. As an outcome of this policy, a strategic plan emerged for the conservation and restoration of Edmonton’s natural systems and the biodiversity they contain (**Figure 13.6**).

Enabling actors and institutional arrangements in local and urban biodiversity conservation has been proven in certain cases to be successful when governments collaborate across different levels to enhance the quality of urban environments for ecological and social benefits. Extensive stakeholder participation on environmental management “may seem very risky, but there is growing evidence that if well designed, these perceived risks may be well worth taking” (Reed 2008). However, fiscal and budget prioritization remain serious challenges for the public administration.

The Edmonton case study illustrates a successful implementation of the Protected Areas System Policy, securing 110ha/year of priority natural areas. Although Edmonton’s Ecological Footprint has decreased, it is still 7.45ha per capita, far above the global average of 2.71ha per capita, and 4.5ha per capita higher than the sustainability indicator of global capacity; this is largely driven by consumption of resources from outside city boundaries.

**Table 13.6: Summary of assessment criteria: Edmonton Natural Area Systems Policy**

| Criterion                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | References                                                                         |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| <b>Success or failure</b>         | The Edmonton 'Report on the Environment 2015' includes several ecological indicators, including naturalization of turf, priority natural areas secured, land secured for natural areas and wetland expansion, and the number of trees managed and cared for by the City Council. Time series data indicate that most indices show positive trends, with increases in the number of trees maintained by the city, land secured for natural areas and reconstructed wetland.                                                                                   |                                                                                    |
| <b>Independence of evaluation</b> | Policy success has been self-assessed with oversight from a City Environmental Management Steering Committee.                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                    |
| <b>Key actors</b>                 | Key actors include the Edmonton City Council and the departments responsible for initiating best practices for biodiversity protection. The Office of Natural Areas coordinates the city's corporate strategic efforts to protect the network. Local communities participate in programmes such as the Master Naturalist, which exchanges knowledge and education for volunteering for stewardship of the natural areas within the city, monitoring of invasive species via citizen science, and participation in governance of a not-for-profit land trust. |                                                                                    |
| <b>Baseline</b>                   | The findings of the City of Edmonton's 2006 'State of Natural Areas' report revealed that its business-as-usual land use would result, over time, in the loss of more than half the area of existing natural systems in Edmonton's tablelands.                                                                                                                                                                                                                                                                                                               | City of Edmonton 2009                                                              |
| <b>Time frame</b>                 | 'The Way We Green Vision: 2040' set out the City of Edmonton's 30-year environmental strategic plan, with an emphasis on resilience and sustainability, and defined 12 goals that need to be reached for Edmonton to achieve a sustainable and resilient future.                                                                                                                                                                                                                                                                                             |                                                                                    |
| <b>Constraining factors</b>       | The city continues to experience significant losses of natural areas as new residents move to Edmonton in unprecedented numbers. Responses to this have been the purchase by the city of valuable lands to protect them from development pressures (see below).                                                                                                                                                                                                                                                                                              | City of Edmonton 2009                                                              |
| <b>Enabling factors</b>           | Leadership within the City Council seems to be strong and sustained in driving through both policy and implementation. Edmonton's City Council authorized a Can\$20 million fund allocation and permit borrowing land trust for the acquisition of forests and wetlands in new neighbourhoods and, as part of a separate initiative, a Can\$1 million per year agreement to purchase wetlands. A strong international profile and reputation may also help in continuing to focus attention on sustaining successes.                                         | City of Edmonton, 2009; Local Governments for Sustainability 2013                  |
| <b>Cost-effectiveness</b>         | The City of Edmonton evaluated the environmental effects, value and structure of Edmonton's urban forest, considering three ecosystem services: cleansing the air; sequestering carbon; and reducing storm water. The average benefit per tree in Edmonton's urban forest was US\$74.73, whereas the cost of caring for each tree is US\$18.38.                                                                                                                                                                                                              | City of Edmonton 2009                                                              |
| <b>Equity</b>                     | The project has contributed to the social integration of immigrants into the life of the city. Land developers have to comply with environmental regulations, and new suburban areas are designed with new green spaces, natural areas and parks for the benefit of communities. However, the increase in the value of land means that buying land for conservation purposes is prohibitively costly for the City trust, especially because landowners are more reluctant to sell.                                                                           |                                                                                    |
| <b>Co-benefits</b>                | Increasing green spaces in urban settings provides additional benefits, including reducing stress, crime and violence and increasing neighbourhood social cohesion. They support a range of benefits associated with psychological, cognitive and physiological health (WHO and SCBD 2015). There are some indications of increased opportunities for renewable energy businesses (Alberta Canada 2017).                                                                                                                                                     | Maas <i>et al.</i> 2009; Garvin, Cannuscio and Branas 2013; Roe <i>et al.</i> 2013 |
| <b>Transboundary issues</b>       | None identified or recorded in reviewing the progress reports                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                    |
| <b>Possible improvements</b>      | Some long-term tracking of a wider range of social as well as environmental benefits would be useful, as would a more formal evaluation by independent peers. There is also a need to incorporate the trade-offs, such as increased land costs, and conflicts between priorities in a city with a population that has increased over the last 25 years.                                                                                                                                                                                                      |                                                                                    |

### 13.3 Indicators: Biodiversity policy

Policy-sensitive indicators provide an interesting way to understand policy implementation (see Chapter 10). Both IPBES and CBD have produced global assessments using a wide variety of indicators; for example, Global Biodiversity Outlook-4 used 55 biodiversity indicators (SCBD 2014; Tittensor *et al.* 2014). For the purposes of the sixth Global Environment Outlook (GEO-6), three global indicators were

selected based on their linkages with the SDGs, national disaggregation and continuity with previous GEOs (see Table 13.7).

Currently, there is a lack of indicators which can adequately capture the links between biodiversity and human health, though ways to improve biodiversity health indicators have been described previously (Huynen, Martens and De Groot 2004; Hough 2014; Sandifer, Sutton-Grier and Ward 2015).

**Table 13.7: Policy-sensitive indicators**

| Indicator                                                                                                                                       | Rationale for selection                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Addressed in Part A                                                                                                                                                                              | Addressed in the case studies                                                                                                                    | Connection with the SDGs or MEAs                                                                                        | Data sources                                                                                      |
|-------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------|
| 1) Proportion of countries adopting relevant national legislation and adequately resourcing the prevention or control of invasive alien species | Links to the Convention on Biological Diversity as an indicator for Aichi Biodiversity Target 9. Indicator is policy-responsive and relevant and was designed as a response indicator. It was used in the fifth Global Environment Outlook (GEO-5) and is a confirmed SDG indicator.                                                                                                                                                                                                                     | <b>Yes:</b> invasive species are dealt with as one of the five main pressures on biodiversity (Section 6.4.2).                                                                                   | <b>Yes:</b> invasives are the subject of the WfW case study from South Africa (Section 13.2.3), which uses PES as a means of tackling invasives. | <b>Aichi Biodiversity Target 9.</b> This is also the indicator for SDG Target 15.8.                                     | IUCN, IUCN SSC, IUCN ISSG, Monash University; bipindicators.net for factsheets, graphs, meta-data |
| 2) Red List Index (impacts of utilization)                                                                                                      | Links to CBD as an indicator for Aichi Biodiversity Target 4. This is a response indicator. It was used in GEO-5 and is relevant to the SDGs. It has global coverage, can be disaggregated, is a quantitative measure based on scientific assessment and has a long data series. Red List (impacts of utilization) was also chosen to demonstrate the degree to which species of direct relevance to human livelihoods and culture are responding to measures to ensure their sustainable use over time. | <b>Yes:</b> subsets of the Red List are used throughout Chapter 6, particularly in Section 6.5 in species section. The Red List Index is the leading global source on species extinction status. | No                                                                                                                                               | <b>Aichi Biodiversity Target 4.</b> Also related to Aichi Targets 3, 6, 7 and 12. Relates to SDGs 8.4, 12.2, 14 and 15. | IUCN Red List Index<br>bipindicators.net for factsheets, graphs, meta-data                        |
| 3) Global Ecological Footprint                                                                                                                  | Links to CBD as an indicator for Aichi Biodiversity Target 4. The indicator tracks pressures. It was used in GEO-5 and is relevant to the SDGs. It is global, based on a long data series and can be disaggregated. This indicator was chosen because an increase in a nation's Ecological Footprint would mean an increase in its population's pressure on biodiversity and an increased risk of biodiversity loss.                                                                                     | <b>Yes:</b> in Section 6.4.1, as a leading driver of biodiversity loss.                                                                                                                          | <b>Yes:</b> the Ecological Footprint of Edmonton is quoted in the policy effectiveness assessment Section 13.2.5.                                | <b>Aichi Biodiversity Target 4.</b> Related to SDG targets 8.4 and 12.2.                                                | Global Footprint Network<br>bipindicators.net for factsheets, graphs, meta-data                   |

### 13.3.1 Indicator 1: Proportion of countries adopting relevant national legislation and adequately resourcing the prevention or control of invasive alien species (SDG Indicator 15.8.1)

Invasive alien species (IAS) may threaten local biodiversity through direct and indirect competition, predation and habitat degradation, and as disease agents and vectors (Pejchar and Mooney 2009; Strayer 2010). They are considered the second greatest threat to biodiversity after land-use change and habitat loss (Section 6.4.2) (Wilcove *et al.* 1998; Bellard, Cassey and Blackburn 2016).

This indicator evaluates the “trends in policy responses, legislation and management plans to control and prevent spread of invasive alien species” (species that have been introduced to an area and have spread beyond the area of introduction) and the “proportion of countries adopting relevant national legislation and adequately resourcing the prevention or control of invasive alien species” (see methodology in Biodiversity Indicators Partnership 2018a) (Figure 13.7 and Figure 13.8).

#### Policy relevance

This indicator directly tracks progress towards global multilateral environmental agreements, and in particular Target 9 of the Aichi Biodiversity Targets. It is also relevant to Aichi Targets 5, 11, 12 and 17 and Goal 15 (Target 15.8) of the SDGs (‘Life on Land’) (UNEP 2015).

**Figure 13.7: Trends in national legislation relevant to the prevention or control of invasive alien species (IAS) for 196 countries reporting to the Convention on Biological Diversity (1967–2016), showing specifically the percentage of countries having a combination of: (i) IAS legislation; (ii) NBSAP targets on IAS; and (iii) IAS targets aligned with Aichi Target 9**

## Causal relations

As more multilateral international agreements relevant to IAS are introduced (such as the Cartagena Protocol, the International Plant Protection Convention and the Agreement on Sanitary and Phytosanitary Measures of the World Trade Organization), the level of national commitment to related policies increases. This, in turn, reflects a greater global commitment to controlling IAS (Biodiversity Indicators Partnership 2018a). Those countries that are party to the CBD have agreed to Aichi Target 17, and policies related to the control of IAS should be addressed in their NBSAPs. This is an example of an international policy trigger and a top-down approach leading to the creation of national IAS regulations. A bottom-up causal relation (the creation of an IAS policy due to an increase in IAS within a country) is more difficult to demonstrate.

Within national IAS-relevant policies, governments may use several policy instruments to reduce IAS. These responses can be quite varied and specific. The WfW programme in South Africa (Section 13.2.3) uses PES to encourage the removal of IAS from waterways by giving monetary incentives to local communities (Buch and Dixon 2009). Other nations may use CCPs, such as the United Kingdom of Great Britain and Northern Ireland plant health policy that imposes strict regulations on and certifications for the import and moving of certain plants, seeds, organic matter and plant products to prevent the introduction and spread of harmful plant pathogens (UK Department for Environmental and Rural Affairs 2014), as well as Australia's well-developed strategic plan (Australia, Invasive Species Council 2015). In addition, island nations may have stronger IAS policies, reflecting a higher presence of endemic species, and ports can be subjected to stronger regulation, such as the recent international Ships Ballast Water and Sediments policy (International Maritime Organization 2017).

Other international and national policies may influence this indicator, especially trade policies. As globalization progresses and international commerce creates new trade routes and markets, new opportunities are created for alien species to establish themselves in new areas (Meyerson and Mooney 2007; Seebens *et al.* 2015). A direct positive link has been shown between the degree of international trade by a nation and the number of IAS (Westphal *et al.* 2008; Hulme 2009; Liebhold *et al.* 2012; Brockerhoff *et al.* 2014).

## Other factors

Climate change, especially in colder regions, poses an IAS risk, as it may lower the barrier to establishment by creating new niche space (Wolkovich *et al.* 2013; Duffy *et al.* 2017). Emerging economies with increasing economic development in tourism, the exotic pet trade and infrastructure projects are also at greater risk of IAS (Hulme 2015).

## 13.3.2 Indicator 2: Red List Index (impacts of utilization)

Humans depend on biodiversity and the use of wildlife in a range of different ways (e.g. hunting, trapping and collecting wild birds for food, sport or feathers). The Red List Index (RLI) (impacts of utilization) shows trends in the status of mammals, amphibians and birds driven by two factors: the negative impacts of utilization (i.e. the use of wildlife leading to a decrease in status) or the positive impacts of measures taken (i.e. controlling or managing the utilization of wildlife

**Figure 13.9: The Red List Index (RLI) for 1980–2017 for mammals, birds and amphibians, showing the trends driven only by utilization (by only including utilized species)**

Source: Biodiversity Indicators Partnership (2018b). Partners: Birdlife International, Kew Gardens, ZSL, IUCN

towards sustainability) (Biodiversity Indicators Partnership 2018b, see Section 6.5.2). **Figure 13.9** shows the RLI (impacts of utilization) for birds, mammals and amphibians from 1980 to 2017.

## Scope and measurement

The indicator is determined from species-level data which may be analysed on several scales (country, region and/or global). The IUCN Red List assigns species to seven categories of relative extinction risk (Extinct to Least Concern, or 'Data Deficient' for poorly known species). This is done using quantitative criteria for species based on population size, area of distribution and rate of decline (Bubb *et al.* 2009). In the 2012 update, the IUCN Red List included assessments for 63,837 species, of which 19,817 were threatened with extinction (SCBD and IUCN 2018). An RLI of 1 means all species in that group are categorized as Least Concern, while an RLI of 0 means that all species in the group are Extinct (Bubb *et al.* 2009). Currently, an RLI can be calculated for birds, mammals, amphibians, corals and gymnosperms. To assess taxonomic groups that are poorly known and/or have a very large number of species, a sampling approach was developed in which 1,500 species are randomly chosen and assumed to represent the larger group (Baillie *et al.* 2008).

For the RLI (impacts of utilization), only species that are utilized by humans (as pets, for food, medicine, materials or other uses) are included. Utilization categories are defined by the IUCN Use and Trade Classification Scheme (version 3.2) (IUCN

2006; Almond *et al.* 2013). The resulting trend can be used to indicate the degree to which consumption is sustainable and the impact of natural resource use is within safe ecological limits. A declining trend indicates that current utilization is unsustainable (negative impact of utilization), while an upward trend means that human use of this group of species is sustainable (positive impact of utilization through measures to control or manage sustainably) (Birdlife International 2012).

#### Policy relevance

The RLI (impacts of utilization) is directly related to Target 4 of the Aichi Biodiversity Targets. It is also directly related to several targets within SDGs 8, 12, 14 and 15 (Biodiversity Indicators Partnership 2018b; UNEP 2015).

#### Causal relations

Policies that limit the utilization or promote sustainable management of species have the potential to directly impact this indicator, though there is little to no published literature demonstrating policy effectiveness. The lack of evidence for policy impact may be partly because the average time for species status to improve by one Red List category is 16 years (Young *et al.* 2014). However, this indicator should be sensitive to economic changes or policies that increase or decrease the price of a species-derived product. For example, a higher market price creates an incentive for greater use of a species by the manufacturer or hunter and, therefore, can put that group of species at greater risk of extinction, reflected in a lower RLI (Ayling 2013). It has been shown that CCPs, such as CITES international trade bans and regulations on poaching products from endangered species, can fail when there are strong economic incentives to continue poaching (Rivalan *et al.* 2007; Conrad 2012). Policies that instead focus on incentivizing and building capacity within communities to sustainably manage wildlife (e.g. as showcased in the Project Predator case study, Section 13.2.2) can decrease the long-term use of and demand for species (Challender and MacMillan 2014), effectively increasing the RLI (impact of utilization). Similarly, modelling has shown that more effective management of protected areas (i.e. design of protected areas, adequacy and appropriateness of management, delivery of objectives; SCBD 2018c) can have a greater positive impact on the RLI than only expanding protected areas (Costelloe *et al.* 2016).

#### Other factors

Other factors include cultural and marketplace trends, such as people not buying items of clothing made using animals (fur, leather, feather down) and the increase in vegetarian/vegan diets in Western countries (Newport 2012; Saner 2016). Both these trends can result in a decrease in the use of species, and an increase in the RLI. Advocacy groups and consumer policies that push for decreases in the use of threatened species play a large role in marketplace trends; for example, consumer awareness campaigns, an increase in the number of organizations certifying environmental sustainability, and government restrictions have combined to dramatically reduce the consumption of shark fins in China in recent years (Fabinyi 2016).

#### Caveats

Empirical data supporting policy effectiveness remain scarce. One study showed that the efforts of a local conservation trust resulted in improving the status of a small set of 17 threatened vertebrate species in Brazil, India, Madagascar, Mauritius and

© Dr Nibedita Mukherjee

Spain (Young *et al.* 2014). However, other studies have shown that the RLI has the potential to exhibit a shifting baseline over the long term. This is because the Red List measures declines in abundance over species-specific time frames, so if populations stabilize, a species may return to a low-risk category despite being at very low population levels (Costelloe *et al.* 2016; Nicholson, Fulton and Collen 2017).

#### 13.3.3 Indicator 3: Ecological footprint

The Ecological Footprint, or Ecological Footprint Accounting, “compares human demand on nature against biocapacity, or nature’s supply” and capacity to regenerate (Rees and Wackernagel 1996). “Demand is measured by the biologically productive area a human population uses for producing the natural resources it consumes and absorbing its waste.” Biocapacity is measured in surface area (Biodiversity Indicators Partnership 2018c). The Ecological Footprint is measured “by taking the amount of biologically productive land and water area, or biocapacity that is required to produce the food, fibre and renewable raw materials an individual, population or activity consumes”. It also takes into account the materials needed to absorb carbon dioxide emissions generated (Global Footprint Network 2018). The Ecological Footprint uses an area-equivalent unit called global hectares (gha); 1 gha represents a biologically productive hectare with world average productivity (Galli 2015). The Ecological Footprint encompasses production and consumption, and each of these comprises the cropland, grazing, forest product, carbon and fish footprints, as well as built-up land (Global Footprint Network 2018). As a population’s pressure on biodiversity grows, so does its Ecological Footprint (see Section 13.2.5 Edmonton case study). The world Ecological

Footprint by component (land type) between 1961 and 2013 is shown in **Figure 13.10**.

### Policy relevance

The Ecological Footprint indicator is directly relevant to Target 4 of the Aichi Biodiversity Targets and to several targets within SDG 8 (8.4) and SDG 12 (12.2).

### Causal relations

There have been many studies on Ecological Footprint Accounting and how it can guide policy creation (e.g. the global Ecological Footprint aiding in the recent adoption of a National Strategy for Sustainable Development in Montenegro (Galli 2015; Galli *et al.* 2018), but few empirical examples of how policy changes have affected the global or national Ecological Footprint. Any policies that reduce or promote sustainable management of resource consumption, land use or carbon emissions will lower the Ecological Footprint, while those policies that directly or indirectly promote increases in these parameters raise it. One study has found that economic globalization drives the Ecological Footprint of consumption, production, imports and exports, while social globalization increases the Ecological Footprint of imports and exports but lowers the Ecological Footprint of consumption and production (Rudolph and Figuree 2017).

### Other factors

Other factors that can influence the Ecological Footprint are environmental events that change the biocapacity of a region (e.g. climate change causing a previously unproductive area to become productive or vice versa), technological advancements

that increase the biocapacity of a region (e.g. heat-resistant genetically modified crops that increase the productivity of an area) or cultural consumer choices that increase or decrease resource consumption (e.g. opting for public transit, walking or biking instead of using motor vehicles).

### Caveats

Although the Ecological Footprint has been widely embraced due to its clear depiction for policymakers of the overuse of ecosystem services (Galli 2015), it has also been criticized because it fails to track human-induced depletion of natural capital stocks. However, the methodology is actively being improved by the Global Footprint Network (Mancini *et al.* 2017).

## 13.4 Conclusions

It is well established that biodiversity is in a crisis and that existing policy and governance measures to conserve biodiversity have not been adequate (see Chapter 6, Executive Summary). This may be because policy responses may be insufficient to counteract the growth of drivers of loss (SCBD 2014).

Evidence suggests that inadequate economic incentives and investments in ensuring effective compliance and enforcement of legal instruments at the national level could lead to ineffective policies and governance (Ambalam 2014). A qualitative study assessing the United Nations Convention to Combat Desertification in Africa identified additional challenges, including a lack of adequate baseline data on desertification, poor monitoring mechanisms and ill-defined

**Figure 13.10: The world Ecological Footprint by component (land type) between 1961 and 2013, measured by number of Earths**

Source: Global Footprint Network (2018).

policy objectives, which hindered compliance (Ambalam 2014). An analysis of the Finnish NBSAP revealed how a range of different forms of responsibility (liability, accountability, responsiveness and care) in different policy sectors could be constructed by introducing new knowledge, providing better process design and building institutional networks (Sarkki *et al.* 2016). However, there remained a lack of intersectoral dialogue despite pro-biodiversity outcomes in other targeted policy sectors, and the responsibilities did not percolate from the environmental administration to other policy sectors. Addressing this cross-sectoral 'responsibility gap' remains a major challenge for effective environmental policies (Mukherjee *et al.* 2015; Sarkki *et al.* 2016). In addition, International Environmental Agreements, in particular, seldom go beyond business-as-usual outcomes

(Kellenberg and Levinson 2014). Diffuse language and the lack of quantitative or measurable goals in many International Environmental Agreements leave signatory countries' actions open to interpretation and prevent rigorous appraisal of their performance in improving the quality of ecosystems.

Biodiversity conservation policy is inherently multifaceted, and it is more vital than ever that a 'big picture' perspective emerges among practitioners and governments. Integrating climate, health and equity issues into efforts to mainstream biodiversity, and developing awareness across sectors of policy commitments, are key to the overall success of the SDGs. Many of the policy initiatives discussed in this chapter can serve as models for scaling up efforts to the global level with appropriate and sustained support from governments.
